Abstract

Viscosity solutions of Hamilton-Jacobi equations need only to be continuous. Here we prove that, in the special case of an one dimensional stationary problem, under quite general assumptions, Lipschitz continuous viscosity solutions have right and left derivatives at every point. Moreover, these derivatives have some kind of continuity properties.

Key words: Hamilton-Jacobi equations, viscosity solutions, regularity

AMS (MOS) Classification Numbers: 35L60, 35L99
Introduction

The theory of nonlinear, first-order partial differential equations of Hamilton-Jacobi type has been substantially developed with the introduction by M.G. Crandall and P.-L. Lions [2] of the class of viscosity solutions, which turns out to be the correct class of generalized solutions for such type of equations. M.G. Crandall, L.C. Evans and P.-L. Lions [1] provided a simpler introduction to the subject, while the book by P.-L. Lions [8] and the review paper by M.G. Crandall and P.E. Souganidis [3] provide a view of the scope of the theory and references to much of the recent literature.

Viscosity solutions need only to be continuous. On the other hand, they satisfy the corresponding equations at every point of differentiability. One would like to know, however, more about the structure of these solutions; for example, if and when there exist regions where viscosity solutions are (piecewise) continuously differentiable. Such kinds of results are of interest not only from the theoretical point of view but also for applications, since they may lead presumably to an understanding of the structure of the singularities of solutions of Hamilton-Jacobi type equations (e.g. the eikonal equation in geometrical optics, etc.).

This paper is concerned with the regularity of a Lipschitz continuous viscosity solution \( u \) of the simple problem

\[
(0.1) \quad u + H(u_X) = v \quad \text{in } (-R,R)
\]

where \( H: \mathbb{R} \to \mathbb{R} \) and \( v: (-R,R) \to \mathbb{R} \) are continuous functions. The results obtained say that under some conditions on \( H \) for every \( x_0 \in (-R,R) \) \( u \) has left and right derivatives at \( x_0 \), which we denote by \( u^-_X(x_0) \) and \( u^+_X(x_0) \) respectively. Moreover, these derivatives are continuous in a sense we make precise later.

Before we state the results we need to introduce some notation. In particular for \( c \in \mathbb{R} \)

\[
H^{-1}([c]) = \{ p \in \mathbb{R} : H(p) = c \}.
\]
Theorem 1: Let \( u \) be a locally Lipschitz continuous viscosity solution of (0.1) where \( H: \mathbb{R} \to \mathbb{R} \) and \( v: (\mathbb{R}, \mathbb{R}) \to \mathbb{R} \) are continuous functions. Assume that for every \( c, M \in \mathbb{R} \) the set
\[
H^{-1}(\{c\}) \cap [-M, M]
\]
is either empty or finite and that the local extremum values (i.e. the local minimum and maximum values) of \( H \) are isolated. Then for every \( x_0 \in (-R, R), u \) is either differentiable or it has left and right derivatives \( u_x^-(x_0) \) and \( u_x^+(x_0) \) at \( x_0 \) respectively. If \( u_x^-(x_0) \neq u_x^+(x_0) \), then
\[
H(u_x^-(x_0)) = H(u_x^+(x_0)) = v(x_0) - u(x_0)
\]
\[\text{and}\]
\[
H(\lambda)(u_x^+(x_0) - u_x^-(x_0)) \geq (v(x_0) - u(x_0))(u_x^+(x_0) - u_x^-(x_0))
\]
for every \( \lambda \in [\min(u_x^-(x_0), u_x^+(x_0)), \max(u_x^-(x_0), u_x^+(x_0))] \).

Remark: The second part of (0.2) above is immediate from the definition of the viscosity solution.

Theorem 2: Under the assumptions of Theorem 1 for every \( x_0 \in (-R, R) \) there exists an \( \alpha = \alpha(x_0) > 0 \) such that:

(i) If \( v(x_0) - u(x_0) \) is not a local extremum value of \( H \), then

\[
u |_{(x_0 - \alpha, x_0)} \in C^1((x_0 - \alpha, x_0)), u |_{[x_0, x_0 + \alpha]} \in C^1([x_0, x_0 + \alpha]) \]

(ii) If \( v(x_0) - u(x_0) \) is a local extremum value of \( H \), then the following are true on \( (x_0 - \alpha, x_0) \) (respectively \( [x_0, x_0 + \alpha] \)). Either

\[ u(x) = v(x) + u(x_0) - v(x_0) \text{ or } u |_{(x_0 - \alpha, x_0)} \in C^1((x_0 - \alpha, x_0)) \]

\[ u |_{[x_0, x_0 + \alpha]} \in C^1([x_0, x_0 + \alpha]) \text{ or } u_x(x) \text{ exists for every } x \in (x_0 - \alpha, x_0) \]

(respectively \( [x_0, x_0 + \alpha] \)) except perhaps a sequence \( x_n \to x_0 \) where \( u_x^-(x_n) \neq u_x^+(x_n) \). In this last case, however, we have

---

(1) \( f |_I \) is the restriction of the function \( f \) on \( I \)

(2) \( C^1(I) \) is the space of continuously differentiable functions defined on \( I \).
\[ \lim_{x \to x_0^-} p(x) = u^{-}(x_0) \quad \text{(respectively)} \quad \lim_{x \to x_0^+} p(x) = u^{+}(x_0) \]
\[ \quad x \in (x_0 - \alpha, x_0] \quad \quad \quad x \in [x_0, x_0 + \alpha) \]

where \( p(x) \in \{ u^{-}(x), u^{+}(x) \} \)

Part (ii) asserts that in the case where \( v(x_0) - u(x_0) \) is a local extremum value of \( H \) one can not expect in general something as simple as Part (i). In particular, it may happen that there exist points arbitrarily close to \( x_0 \) where \( u \) is not differentiable; the left and right derivatives at these points satisfy, however, the continuity property stated above. On the other hand there are cases (for example \( v \equiv 0 \)) where we know that, independently of whether \( v(x_0) - u(x_0) \) is a local extremum of \( H \) or not, \( u \) is continuously differentiable in a suitable neighborhood of any point \( x_0 \) with possible discontinuity of the derivative at \( x_0 \).

Inequality (0.2) is the Oleinik E-condition \([9]\) as it applies to the problem (0.1) (for more details see Section 3). Thus Theorem 1 shows that the condition introduced by M.G. Crandall and P.-L. Lions in [2] to uniquely characterize solutions of Hamilton-Jacobi equations implies in one dimension the necessary condition for uniqueness of piecewise smooth solutions of scalar conservation laws.

The proof of Theorem 1 is based on a "blow-up" argument. More precisely, for \( x_0 \in (-R, R) \) and \( \delta > 0 \) sufficiently small, let \( u^\delta, v^\delta : [-1, 1] \to \mathbb{R} \) be defined by

\[
\begin{align*}
    u^\delta(x) &= \frac{u(x_0 + \delta x) - u(x_0)}{\delta} \\
    v^\delta(x) &= v(x_0 + \delta x).
\end{align*}
\]

(0.3)

It turns out that \( u^\delta \) is a viscosity solution of

\[ \delta u^\delta + H(u^\delta_x) = v^\delta - u(x_0) \quad \text{in} \ (-1, 1). \]
The existence of left and right derivatives of $u$ at $x_0$ follows from an analysis of the possible values of $u_\delta^X$. The regularity of $u$ depends on the properties of $H$ and the fact we work in one space dimension. All these are made precise in Section 2. In Section 1 we prove a kind of intermediate value theorem concerning sub- and superdifferentials of continuous functions defined in one space dimension. This is then used in the same section to obtain information about $u_\delta^X$ as well as Lipschitz continuous viscosity solutions $u^\infty$ of the problem

$$H(u^\infty_X) = v(x_0) - u(x_0) \text{ in } (-R,R).$$

Section 3 describes the analogy with conservation laws.

General results concerning regularity of the value function of control problems were obtained by W.H. Fleming [6]. Very precise and general information about the structure of viscosity solutions of the corresponding to (0.1) evolution problem in $\mathbb{R}x(0,\infty)$ can be obtained by "integrating" the results of C.M. Dafermos [5] concerning the structure of solutions of conservation laws. For some results concerning the regularity of viscosity solution of certain special equations in two space dimensions we refer to R. Jensen [7]. Finally, P. Cannarsa and H.M. Soner [4] recently obtained some regularity results concerning the evolution problem with convex Hamiltonian.

We conclude the introduction with the definitions of sub- and superdifferentials and viscosity solutions. We have:

**Definition 1 ([1],[2]):** Let $f$ be a function from $(a,b)$ into $\mathbb{R}$ and let $x_0 \in (a,b)$. Then the superdifferential of $f$ at $x_0$ is the set, denoted by $D^+f(x_0)$, of $p_0 \in \mathbb{N}$ such that

$$f(x) < f(x_0) + p_0(x-x_0) + o(|x-x_0|)$$

holds. Similarly the subdifferential of $f$ at $x_0$ is the set, denoted by $D^-f(x_0)$, of $p_0 \in \mathbb{N}$ such that

$$f(x) > f(x_0) + p_0(x-x_0) + o(|x-x_0|)$$

holds.
Definition 2 ([1],[2]): A continuous function \( u: I \rightarrow \mathbb{R} \), where \( I \) is an open subset of \( \mathbb{R} \), is a viscosity solution of

\[
F(x,u,u_x) = 0 \text{ in } I
\]

if

\[
F(x,u(x),p) < 0, \quad \forall x \in I, \forall p \in D^+ u(x)
\]

and

\[
F(x,u(x),p) > 0, \quad \forall x \in I, \forall p \in D^- u(x)
\]

In a similar way a continuous function \( u: I \rightarrow \mathbb{R} \) is said to be a viscosity sub-solution (resp. supersolution) of (0.8) if (0.9) (resp. (0.10)) holds.

Section 1

We begin with a lemma which plays the role of an intermediate value theorem concerning sub- and superdifferentials of continuous functions. The result is one dimensional and resembles the properties of Dini derivatives. (In one space dimension there is an obvious relation between sub- and superdifferentials and Dini derivatives). We have:

Lemma 1.1: Let \( f \in C(I) \), where \( I \) is an open interval and \( a, b \in I \) with \( a < b \). The following are true:

(i) If \( p, q \in D^+ f(a) \) and \( p < q \), then, for every \( c \in (p,q) \), there exists \( x_0 \in (a,b) \) such that \( c \in D^- f(x_0) \).

(ii) If \( p, q \in D^- f(a) \) and \( p > q \), then, for every \( c \in (q,p) \), there exists \( x_0 \in (a,b) \) such that \( c \in D^+ f(x_0) \).

Proof: (i) Let \( c \in (p,q) \) and define \( g: I \rightarrow \mathbb{R} \) by

\[
g(x) = f(x) - cx
\]

It is immediate that \( p-c \in D^+ g(a) \), \( q-c \in D^+ g(b) \) and \( p-c < 0 < q-c \).

(3) \( C(I) \) is the space of continuous functions defined in \( I \subset \mathbb{R} \).
Using Definition 1 for $\varepsilon > 0$ sufficiently small we obtain

\[ g(x) < g(a) \text{ on } (a, a + \varepsilon) \text{ and } g(x) < g(b) \text{ on } (b - \varepsilon, b) \]

This implies that $g$ achieves a local minimum at some $x_0 \in (a, b)$, therefore

\[ 0 \in \mathcal{D}g(x_0) \] hence $c \in \mathcal{D}^{-f}(x_0)$

(ii) The proof is similar to the one of (i), therefore we omit it.

We continue with a discussion of the properties of $u$ and $u^\delta$. Let $x_0 \in (-R, R)$. If $u : (-R, R) \to \mathbb{R}$ is locally Lipschitz continuous, then $u^\delta$, $v_\delta : [-1, 1] \to \mathbb{R}$ given by (0.3) are well defined for sufficiently small $\delta > 0$. Moreover, there exists a constant $L = L(x_0) > 0$ such that

\[
\begin{cases}
(i) & |u^\delta(x)| < L \text{ for every } x \in [-1, 1], \\
(ii) & \text{ } u^\delta \text{ is Lipschitz continuous with Lipschitz constant } L.
\end{cases}
\] (1.1)

If $u$ is a viscosity solution of (0.1), then Definitions 1 and 2 imply that $u^\delta$ is a viscosity solution of (0.4). Finally, (1.1)(ii) and the properties of the viscosity solution ([2]), yield

\[
\begin{cases}
u + H(u_x) = v \text{ a.e. in } (-R, R) \\
\text{and} \\
\delta u^\delta + H(u^\delta_x) = v_\delta - u(x_0) \text{ a.e. in } (-1, 1).
\end{cases}
\] (1.2)

The next lemma is concerned with the possible values of $u^\delta_x$. The main idea is that $u^\delta$ being a viscosity solution of (1.2) forces $u^\delta_x$ not to "oscillate" too much. This follows from Lemma 1.1 and Definition 2. More precisely, we have:
Lemma 1.2: Let \( x_0 \in (-R,R) \). Assume that \( H, v \) and \( L \) are as in (1.1) and the statement of Theorem 1. For sufficiently small \( \delta > 0 \) there exists a positive integer \( n = n(\delta) \) such that for \( i = 0,1, \ldots, n \), there exist \( x_i \in [-1,1] \), \( p_i \in H^{-1}((v(x_0) - u(x_0))) \cap [-L,L] \) and mutually disjoint relatively open neighborhoods \( I_{p_i} \) of \( p_i \), in \([-L,L]\) with the properties:

(i) \( -1 = x_0 < x_1 < \ldots < x_{n-1} < x_n = 1 \)

(ii) \( p_1 < p_2 < \ldots < p_{n-1} < p_n \)

(iii) \( \left\{ \begin{array}{ll}
(\alpha) & u^\delta_x \in \mathcal{C} I_{p_i} \ a.e. \ on \ [x_{i-1},x_i] \ for \ every \ i = 1, \ldots, n \\
(\beta) & u^\delta_x \in \mathcal{C} I_{p_{n+1-i}} \ a.e. \ on \ [x_{i-1},x_i] \ for \ every \ i = 1, \ldots,n
\end{array} \right. \)

In the case that (iii)(\( \alpha \)) (respectively (iii)(\( \beta \)) holds, if for some \( i \) \( H(p_i) \) is a local extremum value of \( H \), then it has to be a local minimum (respectively maximum). Moreover, \( H(p) > v(x_0) - u(x_0) \) (respectively \( H(p) < v(x_0) - u(x_0) \)) for every \( p \in [p_1,p_n] \). Finally, if \( n > 2 \), then for \( i = 2, \ldots, n-1 \) \( H(p_i) \) is a local extremum value of \( H \).

Proof: In view of (1.1) and (1.2) we have

\[
|H(u^\delta_x(x)) - (v(x_0) - u(x_0))| < \omega_{v,x_0}(\delta) + \delta L \ for \ a.e. \ x \in [-1,1]
\]

where \( \omega_{v,x_0}(\cdot) \) is the modulus of continuity of \( v \) at \( x_0 \) and \( L \) is given by (1.1). The assumptions on \( H \) imply that the set

(1.3) \( A = H^{-1}((v(x_0) - u(x_0))) \cap [-L,L] \)

contains finitely many points \( q_1 < \ldots < q_m \) for some positive integer \( m \). Moreover, by choosing \( \delta \) sufficiently small we may assume that the restriction of \( H \) on \([-L,L]\) has no local extremum values in \([v(x_0) - u(x_0) - \theta, v(x_0) - u(x_0) + \theta] \) except perhaps \( H(q_i) \), where
\[ \theta = \omega_{v,x_0}(\delta) + \delta L. \]

Finally, for each \( i = 1, \ldots, m \) there exist mutually disjoint relatively open \([-L,L]\) neighborhoods \( I_{q_i} \) of \( q_i \) such that

\[ u^\delta \subset \bigcup_{i=1}^m I_{q_i} \quad \text{for a.e. } x \in [-1,1]. \]

and

\[
\{ H(p) : p \in I_{q_i} \} = \begin{cases} 
(v(x_0) - u(x_0) - \theta, v(x_0) - u(x_0) + \theta), \text{if } H(q_i) \text{ is not a local extremum} \\
[v(x_0) - u(x_0), v(x_0) - u(x_0) + \theta), \text{if } H(q_i) \text{ is a local minimum} \\
(v(x_0) - u(x_0) - \theta, v(x_0) - u(x_0)], \text{if } H(q_i) \text{ is a local maximum.} 
\end{cases}
\]

Let \( \{ p_1 < \ldots < p_n \} \subset A \) be such that for each \( i = 1, \ldots, n \) there exists an \( x \in (-1,1) \) with \( u^\delta(x) \in I_{p_i} \). If \( n = 1 \), there is nothing to show. If \( n > 2 \), let \( x, y \in (-1,1) \) be such that \( u^\delta(x) \in I_{p_1} \), \( u^\delta(y) \in I_{p_n} \). Next we assume that \( x < y \). Lemma 1.1(i), Definition 2 and (0.4), (1.1) yield

\[ H(c) > v(x_0) - u(x_0) - \theta \quad \text{for every } c \in [u^\delta(x), u^\delta(y)]. \quad (1.4) \]

This implies that \( H \) does not attain a local minimum value on \([p_1, p_n]\) except perhaps on some element of \( A \) and that \( H(c) > v(x_0) - u(x_0) \) for every \( c \in [p_1, p_n] \). If there exists \( z \in (-1,x) \) such that \( u^\delta(z) \in I_{p_i} \) for \( i > 1 \), then Lemma 1.1(ii), Definition 2 and (0.4), (1.1) yield

\[ H(c) > v(x_0) - u(x_0) + \theta \quad \text{for every } c \in [u^\delta(x), u^\delta(z)]. \quad (1.5) \]

Combining (1.4), (1.5) and the way \( \delta \) was chosen we see that \( H \) must be constant on \([u^\delta(x), \min(u^\delta(y), u^\delta(z))]\) which is a contradiction. This shows that there exists \( x_1 \in (-1,1) \) such that \( u^\delta(a) \in I_{p_1} \) for a.e. \( a \in [-1,x_1] \). If there exists \( w \in (y,1) \) such that \( u^\delta(w) \in I_{p_j} \) for \( j < n \), arguing as above we again obtain a contradiction. So there exists \( x_{n-1} \in (-1,1) \) such that \( u^\delta(a) \in I_{p_n} \) for a.e. \( a \in [x_{n-1},1] \). Next we reason in a similar way on \([x_1, x_{n-1}]\) and thus we obtain statements (i), (ii) and (iii)(a). Finally, it is immediate that for any two \( p_i, p_j \) with \( i < j \), \( H \) cannot attain a local minimum on \((p_i, p_j)\), therefore if \( H(p_k) \) is a local extremum value for \( i < k < j \), it has
to be a local minimum.

Case (iii)(β) follows in exactly the same way if \( x > y \) above.

The next result refines the information given by Lemma 1.2. In particular, it shows that as the whole family \( \delta+0 \) either \( n = 1 \) with \( p_1 \) independent of \( \delta \) or \( n = 2 \) with \( x_1 = 0 \) and \( p_1, p_2 \) independent of \( \delta \). For notational simplicity in what follows we denote all subsequences of the family \( \delta+0 \) in the same way as the family. We have:

**Lemma 1.3:** Let \( x_0 \in (-R, R) \) and \( H, v, L \) and \( A \) as in (1.3) and Lemma 1.2. Then there exist \( p, q \in A \) (independent of \( \delta \)) such that along the whole family \( \delta+0 \) either

\[
(1.6) \quad u_x^\delta \in I_p \text{ for a.e. } x \in [-1, 1]
\]

or

\[
(1.7) \quad u_x^\delta \in I_p \text{ for a.e. } x \in [-1, 0] \text{ and } u_x^\delta \in I_q \text{ for a.e. } x \in [0, 1],
\]

where \( I_p, I_q \) are the neighborhoods of \( p, q \) respectively defined in the proof of Lemma 1.2. Moreover, if (1.7) holds, then there exists a constant \( c > 0 \) such that:

\[
(1.8) \quad \begin{cases} 
\text{If } p < q \text{ (respectively } p > q), \text{ then } H \text{ does not assume any values smaller} \\
\text{ (respectively larger) than } v(x_0) - u(x_0) - c \text{ (respectively } v(x_0) - u(x_0) + c). \\
\text{If } v(x_0) - u(x_0) \text{ is a local extremum value of } H \text{ in either } I_p \text{ or} \\
I_q, \text{ it has to be a local minimum (respectively maximum).}
\end{cases}
\]

**Proof of Lemma 1.3:** We assume that there exists a subsequence \( \delta+0 \) such that

(iii)(a) of Lemma 1.2 holds. (If such a subsequence does not exist, then

(iii)(β) of Lemma 1.2 holds along the whole family \( \delta+0 \). In this case, we argue

in a similar fashion). The fact that \( A \) has finitely many points implies that
along a further subsequence $\delta \downarrow 0$ we have $n(\delta) = n$ and for $i = 1, \ldots, n$, where $n$ and $p_i \in A$ are independent of $\delta$.

If $n = 1$, then $u^\delta_x \in I_{p_i}$ for a.e. $x \in [-1,1]$. This yields $u_x \in I_{p_i}$ for a.e. $x \in [x_0 - \delta, x_0 + \delta]$ as $\delta \downarrow 0$. For any arbitrary $\hat{\delta} > 0$ such that $\hat{\delta} \leq \delta_0$, where $\delta_0$ is the largest element of the above subsequence, we have $[x_0 - \hat{\delta}_1, x_0 - \hat{\delta}] \subset [x_0 - \delta_0, x_0 - \delta_0]$, thus $u^\delta_x \in I_{p_i}$ for a.e. $x \in [-1,1]$.

If $n \geq 2$ we first show that as $\delta \downarrow 0$, $x_1 = x_1(\delta) > 0$. Indeed if not, then along a subsequence $\delta \downarrow 0$ we must have $-1 < x_1 < 0$. This implies that as $\delta \downarrow 0$ $u^\delta_x \in I_{p_1}$ for a.e. $x \in [x_0 - \delta, x_0 + \delta]$ and $u_x \in \bigcup_{i=1}^{n} I_{p_i}$ for a.e. $x \in [x_0 + \delta x_1, x_0 + \delta]$ or equivalently $u_x \in I_{p_1}$ for a.e. $x \in [x_0 - \delta, x_0 + \delta x_1]$ and $u_x \in \bigcup_{i=1}^{n} I_{p_i}$ for a.e. $x \in [x_0 + \delta x_1, x_0 + \delta]$ where we may assume without any loss of generality that the neighborhoods $I_{p_i}$ above are independent of $\delta$. Next observe that $\delta x_1(\delta) \to 0$. Passing, if necessary, to a further subsequence, we may assume that $\delta x_1(\delta)$ strictly increases to 0 as $\delta \downarrow 0$. Let $\delta_1 < \delta_2$ be such that $\delta_1 x_1(\delta_1) > \delta_2 x_1(\delta_2)$. The above analysis implies that $u_x \in I_{p_1} \cap \bigcup_{i=1}^{n} I_{p_i}$ for a.e. $x \in [x_0 + \delta_2 x_1(\delta_2), x_0 + \delta_1 x_1(\delta_1)]$ which is a contradiction.

A similar argument shows that along a further, if necessary, subsequence $\delta \downarrow 0$, $x_{n-1}(\delta) < 0$. But then we have $n=2$ and $x_1 = 0$. For the general $\delta > 0$ we argue as in the case where $n=1$. Finally, the rest of the assertions follow from Lemma 1.2, and its proof, thus we omit the details.

We conclude this section discussing the nature of Lipschitz continuous viscosity solutions of (0.5). The results are very much similar to the ones of Lemma 1.2. For the proof of Theorem 1, however, we only need a less precise qualitative assertion which we give in the following lemma. Since the proof is similar to and simpler than the one of Lemma 1.2 we omit it. We have:
Lemma 1.4: Let $u^\infty$ be a Lipschitz continuous viscosity solution (0.5). Assume that $H$ is as in the statement of Theorem 1. Then $u^\infty$ is linear or piecewise linear with finitely many corners.

Section 2

We begin with the proof of Theorem 1. As usual we denote subsequences in the same way as sequences. We have:

Proof of Theorem 1: Relation (1.1) yields that the family $\{u^\delta: \delta>0\}$ is precompact in $[-1,1]$, that is along subsequences $u^\delta$ converge uniformly to Lipschitz continuous functions $u^\infty:[-1,1] \to \mathbb{R}$ which are ([2]) viscosity solutions of (0.5). Such solutions are described by Lemma 1.4. Here we use Lemma 1.3 to obtain that $u^\infty$ is unique and either linear or piecewise linear with only one corner at $x = 0$, hence the existence of $u^\pm_x(x_0)$.

To this end, assume that $x_0$ is such that (1.6) holds for $\delta>0$. Consider any $u^\infty:[-1,1] \to \mathbb{R}$ which is a possible limit of $\{u^\delta: \delta>0\}$ and suppose that there exist $x_1,x_2 \in [-1,1]$ and $\varepsilon \in A \setminus \{p\}$ such that $x_1 < x_2$ and $u^\infty(x) = \varepsilon x$ on $[x_1,x_2]$. We have

$$(u^\delta(x_2) - u^\infty(x_2)) - (u^\delta(x_1) - u^\infty(x_1)) = \int_{x_1}^{x_2} (u^\delta_y(y) - \varepsilon) dy.$$

The left hand side above tends to zero along a subsequence but the right hand side does not, thus $u^\infty(x) = px$ on $[-1,1]$ and $u^\infty_x(x_0) = p$. In the case that (1.7) holds for $\delta>0$ a similar argument shows that

$$u^\infty(x) = \begin{cases} px & \text{for } x \in [-1,0] \\ qx & \text{for } x \in [0,1]. \end{cases}$$

and, thus, the existence of $u^\pm_x(x_0)$. Finally, the first part of (0.2) is immediate from the properties of $u^\infty$. 
We continue with Theorem 2. The main step in the proof is to reduce to the case where we can invert $H$. If $H^{-1}_\alpha$ is an appropriate branch of $H^{-1}_\alpha$ and $u_\alpha = H^{-1}_\alpha(v-u)$ a.e. in a neighborhood of $x_0$, then the continuity of the right hand side will imply the result. Unfortunately this is not always possible, thus we have to deal with several cases. We have:

**Proof of Theorem 2:** We begin with the case where $v(x_0)-u(x_0)$ is not a local extremum value of $H$. If $u_x(x_0) = p$ exists, then, for $x$ sufficiently close to $x_0$, $H^{-1}$ is defined in a neighborhood of $u(x_0) - v(x_0)$ with range some open neighborhood $I_p$ of $p$ and 

$$u(x) = u(x_0) + \int_{x_0}^{x} H^{-1} (v(y) - u(y))dy$$

which implies the result. If $u_{x}^{-}(x_0) = p \neq u_{x}^{+}(x_0) = q$, then we have two branches $H^{-1}_p$ and $H^{-1}_q$ of the inverse of $H$ defined in a neighborhood of $v(x_0) - u(x_0)$ with values in some open disjoint neighborhoods $I_p$ and $I_q$ of $p$ and $q$ respectively. Again we have 

$$u(x) = u(x_0) - \int_{x}^{x_0} H^{-1}_p (v(y) - u(y))dy \text{ for } x < x_0$$

and 

$$u(x) = u(x_0) + \int_{x_0}^{x} H^{-1}_q (v(y) - u(y))dy \text{ for } x > x_0$$

thus the result.

If $u(x_0) - v(x_0)$ is a local extremum of $H$ the argument is more complicated. We have to examine the following cases:

**Case 1.** $u_{x}^{-}(x_0) = p < q = u_{x}^{+}(x_0)$

We first assume that $H$ attains a local extremum only at $q$, which by Lemma 1.3 has to be a minimum. Moreover, $H$ is invertible in a neighborhood of $v(x_0) - u(x_0)$ with values in some $I_p$. Finally, Lemma 1.3 also yields the existence of an $\alpha > 0$ such that $u_x(x) \in I_p$ for a.e. $x \in (x_0 - \alpha, x_0]$ and...
$u(x) \in I_q$ for a.e. $x \in (x_0, x_0 + \alpha)$ where $I_q$ is an appropriate open neighborhood of $q$. For $x < x_0$ we argue as before. For $x > x_0$ we define

$$I_{q,1} = \{ \varepsilon \in I_q : \varepsilon < q \} \text{ and } I_{q,2} = \{ \varepsilon \in I_q : \varepsilon > q \}.$$ 

If, for a.e. $x \in [x_0, x_0 + \alpha)$, $u_x(x)$ either belongs to $I_{q,1}$ or $I_{q,2}$, then we can again invert $H$ and argue as before. If this does not happen, then we cannot necessarily show that $u$ is of class $C^1$ for $x > x_0$ in general. On the other hand, we are able to obtain some other information concerning $q$. In particular, we can find $x_0 < x < y < x_0 + \alpha$ arbitrarily close to $x_0$ such that

$u_x(x) \in I_{q,1} \setminus \{q\}$ and $u_x(y) \in I_{q,2} \setminus \{q\}$. Then Lemma 1.1 implies the existence of $z$ such that $x < z < y$ and $q \in D\tilde{u}(z)$. This yields $u(z) + H(q) > v(z)$.

But $u(x) + H(u_x) = v(x)$ and $H(q) = H(u_x)$ for a.e. $x \in [x_0, x_0 + \alpha)$.

The continuity of $u$ and $v$ then imply

$$u(x) - u(x_0) < v(x) - v(x_0) \text{ for every } x \in [x_0, x_0 + \alpha].$$

Combining all the above we obtain

$$u(z) - u(x_0) = v(z) - v(x_0).$$

and, moreover,

$$(2.1) \quad q = \lim_{x \to x_0} \frac{v(x) - v(x_0)}{x - x_0}.$$ 

Next define the sets

$$I = \{ x \in [x_0, x_0 + \alpha] : u(x) - u(x_0) = v(x) - v(x_0) \}$$

and

$$\Pi = \{ x \in [x_0, x_0 + \alpha] : u(x) - u(x_0) < v(x) - v(x_0) \}.$$ 

We first investigate the behavior of $u$ on $I$, which is closed and nonempty. Let $z \in I$. By Theorem 1 $u^+_x(z)$ exists and lies in a small neighborhood of $q$ provided that $\alpha$ is sufficiently small. On the other hand, since
\[ H(u^+_x(z)) = v(z) - u(z) = v(x_0) - u(x_0) \] the properties of \( H \) yield
\[ u^+_x(z) = q, \text{ thus } u \text{ is differentiable at } z. \] If \( I = [x_0, x_0 + \alpha] \) there is nothing to show. If not, then \( \Pi \) is a nonempty open set, therefore it can be written as countable union of mutually disjoint open intervals \( J_m \), i.e.
\[ \Pi = \bigcup_m J_m. \] On each \( J_m = (a_m, b_m) \) we have
\[ u(x) - u(x_0) < v(x) - v(x_0) \]
and
\[ u(a_m) - u(x_0) = u(b_m) - u(x_0) = v(a_m) - v(x_0) = v(b_m) - v(x_0) = u(x_0) - v(x_0). \]

It is easy to see arguing as before that for every \( x \in J_m \) either \( u^+_x(x) \in I_{q,1}\setminus\{q\} \) or \( u^+_x(x) \in I_{q,2}\setminus\{q\} \). Moreover, Lemma 1.1 yields that there exists at most one \( c_m \in J_m \) such that
\[ u_x(x) \in I_{q,2}\setminus\{q\} \text{ for a.e. } x \in (a_m, c_m) \]
and
\[ u_x(x) \in I_{q,1}\setminus\{q\} \text{ for a.e. } x \in (c_m, b_m). \]

Arguments similar to the ones at the beginning of the proof imply that
\[ u \in C^1((a_m, c_m)) \text{ and } u \in C^1((c_m, b_m)) \]
Moreover, \( u^-_x(c_m) \neq u^+_x(c_m) \) and \( \lim_{x \to a_m} u_x(x) = \lim_{x \to b_m} u_x(x) = q. \) This completes the proof.

If \( p \) is a local minimum but \( q \) is not or when both are local minima we argue as above changing (2.1) appropriately.

The remaining two cases

**Case 2:** \( u^-_x(x_0) = p > u^+_x(x_0) = q \)
and

**Case 3:** \( u_x(x_0) = p \)

follow in the same way, therefore we omit the details.
We conclude this section by showing how one can overcome the above difficulties in the special case where \( v \equiv 0 \). We have:

**Proposition 2.1:** Under the assumptions of Theorem 2 but with \( v \equiv 0 \), for every \( x_0 \in (-R,R) \) there exists an \( \alpha = \alpha(x_0) > 0 \) such that

\[
\begin{align*}
 u|_{(x_0 - \alpha, x_0]} &\in C^1((x_0 - \alpha, x_0]) \quad \text{and} \quad u|_{[x_0, x_0 + \alpha]} \in C^1([x_0, x_0 + \alpha])
\end{align*}
\]

**Proof:** We continue with the proof of Case 1 of Theorem 2. We want to claim that \( u \equiv u(x_0) \) on \([x_0, z]\). Indeed if not then there exists a \( w \in (x_0, z) \) such that \( u(w) < u(x_0) = u(z) \) and \( 0 \in D^-u(w) \). But then

\[
u(w) + H(0) > 0\]

On the other hand, by (2.1),

\[
q = 0 \quad \text{and} \quad H(q) = -u(x_0)
\]

Therefore

\[
u(w) > u(x_0)
\]

which leads to a contradiction, thus the result. The other cases can be treated similarly.

**Section 3**

In this section we use Theorem 1 to illustrate the relation between the notion of *viscosity solution* and the *E condition* introduced in [9] by O.A Oleinik. Throughout the section we assume:

\[
\begin{align*}
(i) \quad & H, v \text{ are continuously differentiable} \\
(ii) \quad & u(x_0) - v(x_0) \text{ is not a local extremum value of } H.
\end{align*}
\]

Let \( w: (-R,R) \to R \) be defined by

\[
w(x) = u_x(x) \text{ for a.e. } x \in (-R,R)
\]
In view of (3.1) and the results of the previous section, at every point where 
\( u_x \) exists, \( w \) is continuous and it satisfies

\[
(3.2) \quad w + (H(w) - v)_x = 0 \quad \text{a.e. in} \ (-R,R)
\]

Moreover, at points where \( u_x \) does not exist, \( w \) has right and left limits \( w_+ \) and \( w_- \) respectively which satisfy

\[
\begin{cases}
H(w_+) = H(w_-) = v(x_0) - u(x_0) \\
\text{and}
\end{cases}
\]

\[
(3.3) \quad H(p) < H(w_+) \quad \text{for every} \quad p \in [w_+, w_-] \quad \text{if} \quad w_+ > w_-
\]

or

\[
H(p) > H(w_-) \quad \text{for every} \quad p \in [w_-, w_+] \quad \text{if} \quad w_+ > w_-
\]

Relation (3.3), however, is the \( E \) condition, as it applies to (3.2). Indeed let

\[
x(w) = \frac{(H(w_+) - v(x_0)) - (H(w_-) - v(x_0))}{w_+ - w_-} (w - w_+) + H(u_+) - v(x_0)
\]

We say (cf. O.A. Oleinik [9]) that a solution \( w \) of (3.2) satisfies the \( E \) condition, if at all points of discontinuity \( x_0 \) of \( w \), the following is satisfied: If \( w_+ > w_- \), then \( x(w) < H(w) - v(x_0) \) for all \( w \in [w_-, w_+] \) and if \( w_- > w_+ \), then \( x(w) > H(w) - v(x_0) \) for all \( w \in [w_+, w_-] \).
