Abstract

We show that second-order superintegrable systems in 2d and 3d Euclidean space generate both exactly solvable (ES) and quasi-exactly solvable (QES) problems in quantum mechanics via separation of variables, and demonstrate the increased insight into the structure of such problems provided by superintegrability. A principal advantage of our analysis using nondegenerate superintegrable systems is that they are multiseparable. Most past separation of variables treatments of QES problems via partial differential equations have only incorporated separability, not multiseparability. Also, we propose another definition of ES and QES. The quantum mechanical problem is called ES if the solution of the Schrödinger equation, can be expressed in terms of hypergeometric functions $_mF_n$ and is QES if the Schrödinger equation admits polynomial solutions with coefficients necessarily satisfying a three-term or higher order of recurrence relations. In three dimensions we give an example of a system that is QES in one set of separable coordinates, but is not ES in any other separable coordinates. This example encompasses Ushveridze’s 10th order polynomial QES problem in one set of separable coordinates and also leads to a 4th order polynomial QES problem in another separable coordinate set.
1 Introduction

It is well known that $N$-dimensional nonrelativistic quantum systems described by the Hamiltonian

$$\mathcal{H} = -\frac{1}{2} \sum_{i=1}^{N} \frac{\partial^2}{\partial x_i^2} + V(x_1, x_2, ..., x_N)$$  \hspace{1cm} (1)$$

are integrable if there exist $N$ linearly independent and global differential operators $\mathcal{I}_\ell$, $\ell = 0, 1, ..N - 1$ and $\mathcal{I}_0 = \mathcal{H}$, commuting with the Hamiltonian (1) and with each other

$$[\mathcal{I}_\ell, \mathcal{H}] = 0, \quad [\mathcal{I}_\ell, \mathcal{I}_j] = 0, \quad \ell, j = 1, 2, ...N - 1. \hspace{1cm} (2)$$

This particular class of integrable systems is called (maximally) superintegrable (this term was introduced first by S.Rauch-Wojciechowski in [1]) if it is integrable and, also, possesses $2N - 1$ functionally independent differential operators (integrals of motion). The additional $N - 1$ integrals $\mathcal{L}_k$, commute with the Hamiltonian

$$[\mathcal{L}_k, \mathcal{H}] = 0, \quad k = 1, 2, ...N - 1, \hspace{1cm} (3)$$

but not necessarily with each other. (These definitions have obvious classical analogs for the classical Hamiltonian.) Three examples of this kind have been well-known for a long time, viz. the Kepler-Coulomb problem, the isotropic harmonic oscillator, and the nonisotropic oscillator with commensurable frequencies.

The existence of additional quantum integrals of motion for these systems leads to many interesting properties not shared by integrable systems. In classical mechanics the corresponding additional integrals of motion have the consequence that in the case of superintegrable systems in two dimensions and maximally superintegrable systems in three dimensions all finite trajectories are found to be periodic.

One of the most important properties for many superintegrable systems (particularly second-order systems where there are $2N - 1$ functionally independent quadratic constants of the motion) is multiseparability, i.e., the separation of variables for the Hamilton-Jacobi and Schrödinger equations in more than one orthogonal coordinate system [2, 3, 4, 5, 6, 7, 8]. (Each separable coordinate system is associated with $N$ commuting second-order constants of the motion.) For instance, the isotropic harmonic oscillator in three dimensions is separable in eight coordinate systems, namely in Cartesian, spherical, circular polar, circular elliptic, conical, oblate spheroidal, prolate spheroidal, and ellipsoidal coordinates. The Kepler-Coulomb potential is separable in four coordinate systems, namely in conical, spherical parabolic, and prolate spheroidal coordinates.

A systematic search for such systems in two- and three-dimensional Euclidean space was started in the pioneering work of Smorodinsky and Winternitz with collaborators in [9, 10, 11] and was continued in [12]. Particularly, in [10] it was shown that in two-dimensional real Euclidean space there exist four superintegrable potentials, three of which could be considered as the singular generalization of Kepler-Coulomb, circular oscillator and anisotropic oscillator systems. These results were extended for two- and three-dimensional spaces with constant curvature (both positive and negative) [13], and on the complex two-dimensional sphere and
Euclidean space \[14, 15, 16, 17, 18\]. The program is continuing for various conformally flat space spaces \[19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 5, 6, 7\].

In the last fifteen years superintegrable systems have become a subject of investigation from many points of view: in \[13, 18, 31, 32\] via the path integral approach, in \[19, 21, 22\] by solving the Schrödinger equation with the help of the Niven ansatz \[33\], in \[34, 35, 36, 37, 38, 39\] from the purely algebraic approach, and generally in \[40\]. As has been shown by a number of authors, many superintegrable systems generate an algebraic structure which may be considered as a nonlinear extension of the Lie algebra (in classical mechanics Poisson algebras), namely a quadratic algebra. The general form of quadratic algebras, which are encountered in the case of two-dimensional quantum superintegrable systems has been investigated \[39, 5, 6\].

Particularly useful is the exact solvability of many superintegrable systems. Essentially, this means that after any separation of variables each of the separated ordinary differential equations admits an exact solution. However, the term exact solvability is defined differently by different authors. In \[41, 42\] (see also the recent paper \[43\]) we read that “an exactly solvable quantum mechanical system can be characterized by the fact that in its solution space one can indicate explicitly an infinite flag of functional linear spaces, which is preserved by the Hamiltonian” or the “Hamiltonian is exactly solvable if its spectrum can be calculated algebraically”. Indeed, in spite of an “intuitive” understanding of the term exactly solvable, no universal definition exists up to now.

On the other hand there are limiting cases of well-known one-dimensional exactly solvable systems, namely the harmonic oscillator and Coulomb problems with \(\gamma/x^2 (\gamma > -1/4)\) interaction, Morse potential, trigonometric and modified Pöschl-Teller potentials, trigonometric and hyperbolic Manning-Rosen potentials \[44, 45\], and the Natanson potential \[46\]. All these potentials have the general property that the Schrödinger spectral problem has an explicit formula for the whole energy spectrum including the continuous spectrum, and the eigenfunctions (up to the asymptotic ansatz or gauge transformations \[41, 42\]) are of hypergeometric type \(1 F_1, 2 F_1\). For the bound states we have solutions in term of classical polynomials \[47\] whereas for continuous states just infinite series. Moreover, hypergeometric functions describe both the continuous quantum systems as well as the finite systems and appear also as solutions of related difference equations, for instance, the finite one- and two-dimensional oscillator expressed in terms of discrete variables polynomials: Krawtchuk, Meixner and Hahn \[48\]. The standard definitions of exact solvability do not include many of these systems.

Thus, we propose another definition of exact solvability: a quantum mechanical system is called exactly solvable if the solutions of the Schrödinger equation, can be expressed in terms of hypergeometric functions \(m F_n\). (Basically, we are requiring that the coefficients in power series expansions of the solutions satisfy two-term recurrence relations, rather than recurrence relations of higher order.) It is obvious, that an \(N\)-dimensional Schrödinger equation is exactly solvable if it is separable in some coordinate system and each of the separated equations is exactly solvable. Further, We say that a superintegrable system is exactly solvable if is exactly solvable in at least one system of coordinates.

At first sight, such a definition of exactly solvable problems may seem too narrow, but it leads us to distinguish two kind of models: 1) those which it is possible to study analytically and 2) those which can be solved numerically via the solution of algebraic equations.

The process of separation of variables in the \(N\)-dimensional Schrödinger equation leads to ordinary differential equations having as solutions many of the special functions of mathemati-
cal physics. A complication of the separated equations involves the $N$ separation constants. In general we have a multiparameter eigenvalue problem [49]. It is possible to distinguish three different cases, namely when there is complete, partial or non-separability of the separation constants. It is obvious that in the case of complete separability (of separation constants) the initial $N$-dimensional Schrödinger equation splits into $N$ independent second-order differential equations, each involving a single separation parameter. This situation occurs, for instance, in the case of separation of variables in the Helmholtz (free Schrödinger equation, which is also superintegrable) or the Schrödinger equation for the harmonic oscillator in Cartesian coordinates. The second “extremal” case, when complete non-separability exists, is realized, in separation of variables for the same problems but in ellipsoidal coordinates. In the last case each separated second-order differential equation contains simultaneously all separation constants (usually depending on dimensional or non-dimensional parameters) [3, 4], for which the simultaneous quantization becomes nontrivial.

The standard method of solution of a second-order ordinary differential equation, obtained after separation of variables in $N$ - dimensional Schrödinger equations, involves (after taking into account the asymptotic ansatz) expansions around one of the singular points of the differential equation (the standard power series method [50], or the so-called Hill-determinant method [51]). The problem reduces to the solution of the recurrence relations for the expansion coefficients. If one can express the equation in a form such that the coefficients obey a two-term recurrence relation, then the corresponding solution can be written in closed or analytic form or in terms of hypergeometric functions and we have an exactly solvable problem. Such situations occur when separation of variables for superintegrable systems is possible in subgroup type coordinate (spherical, cylindrical and Cartesian) [52] and often in parabolic type coordinates. This method is also powerful when separation of variables is possible in non-subgroup systems of coordinates such as spheroidal or elliptic types. In this case we arrive at high-order recurrence relations, the subsequent analysis of which, allows us to investigate the behavior of the solution and to determine if polynomial solutions exist.

There is another general approach for solving the Schrödinger equation by exploring the Niven - type ansatz [33], based on the existence of polynomial solutions. According to this method the complete solution can be constructed without direct separation of variables and computed in terms of the zeros of the corresponding polynomial. This method has been used in papers [19, 21, 22] for the investigation of two- and three-dimensional superintegrable systems in Euclidean and curved spaces. We illustrate the difference between systems that are merely separable and those that are superintegrable. Consider the problem of motion in the plane for a charged particle with two fixed Coulomb centers with coordinates $(\pm D/2, 0)$ (the so-called plane two center problem)

$$V(x, y) = -\frac{\alpha_1}{\sqrt{y^2 + (x + D/2)^2}} - \frac{\alpha_2}{\sqrt{y^2 + (x - D/2)^2}}$$

This system is not superintegrable and separation of variables is possible only in two-dimensional elliptic coordinates (see eq. (70)). Upon the substitution $\psi(\nu, \mu; D^2) = X(\nu; D^2)Y(\mu; D^2)$ and the separation constant $A(D)$, the Schrödinger equation splits into a system of two ordinary differential equations

$$\frac{d^2X}{dv^2} + \left[ \frac{D^2E}{2} \cosh^2 \nu + D(\alpha_1 + \alpha_2) \cosh \nu + A(D) \right] X = 0,$$
\[
\frac{d^2 Y}{d\mu^2} - \left[ \frac{D^2 E}{2} \cos^2 \mu + D(\alpha_1 - \alpha_2) \cos \mu + A(D) \right] Y = 0. \tag{6}
\]

Both equations (5)-(6) belong to the class of non-exactly solvable problems. In general polynomial solutions do not exist even for the case of discrete spectrum \( E < 0 \), and each of the wave functions \( X(\nu; D^2) \) and \( Y(\mu; D^2) \) is expressed as an infinite series with a three-term recurrence relation.

Let us now put \( \alpha_2 = 0 \). Then the potential (4) transforms to the ordinary two-dimensional (2d) hydrogen atom problem, which is well-known as a superintegrable system [53, 54, 55] with dynamical symmetry group \( SO(3) \), and admits separation of variables in three systems of coordinates: polar, parabolic and elliptic. In this case we can see that the separation equations (5) and (6), namely

\[
\frac{d^2 X}{d\nu^2} + \left[ \frac{D^2 E}{2} \cosh^2 \nu + D\alpha_1 \cosh \nu + A(D) \right] X = 0, \tag{7}
\]

\[
\frac{d^2 Y}{d\mu^2} - \left[ \frac{D^2 E}{2} \cos^2 \mu + D\alpha_1 \cos \mu + A(D) \right] Y = 0. \tag{8}
\]

transform into each other by the change \( \mu \leftrightarrow i\nu \). Thus separation of variables in elliptic coordinates for the 2d hydrogen atom gives two functionally identical one-dimensional Schrödinger type equations with two parameters: coupling constant \( E \) and energy \( A(D) \) (correspondingly energy and separation constant for 2d), but one defined on the real and the other on the imaginary axis. In other words, instead of the systems of differential equations (7)-(8), the problem reduces to solving only one of the equations (7) or (8) for which the "domain of definition" is the complex plane. The requirement of finiteness for the wave functions in the complex plane permits only polynomial solutions (see for details [56]). As result we obtain simultaneous quantization of the energy spectrum

\[
E_n = -\frac{\alpha_1^2}{2(n + 1/2)^2}, \quad n = 0, 1, 2, \ldots \tag{9}
\]

and the elliptic separation constant \( A_s(D) \) where \( s = 0, 1, 2, \ldots \) as a solution of an \( n \)th-degree algebraic equation). The polynomial solution is defined by a finite series with three-term recurrence relations for the coefficients. They cannot be considered as exactly solvable and can be investigated only numerically. A similar situation occurs, for instance, in the case of the two-center problem in three-dimensional Euclidean space (the so-called prolate spheroidal radial and angular Coulomb wave functions) [57] and three-dimensional sphere (Heun wave functions) [58], where after eliminating one of the Coulomb centers the problems reduce to superintegrable systems admitting only polynomial solutions. These (and many other) examples suggest a deep connection of the notion of superintegrability and existence of polynomial solutions of the corresponding Schrödinger equation.

We note that each of equations (7) or (8) has the form of a one-dimensional Schrödinger equation with the parameter \( E \) and eigenvalue \( A(D) \), and could be separately considered in the

\(^{1}\)To be completely correct let us note that polynomial solutions exist only for special values of parameters \( \alpha_1, \alpha_2 \) and \( R \).
regions $\mu \in [0, 2\pi]$ or $\nu \in [0, \infty)$, correspondingly. Then for arbitrary values of constant $E$ (for example when $E_n = 0 \ (n \to \infty)$ the equations (7) and (8) transforms to periodic and modified Mathieu equations, which are non-exactly solvable) the solutions of eqs. (7) or (8) expressed via infinite series and only on the “energy surface” of the 2d hydrogen atom (9), split into polynomial and nonpolynomial sectors (each of these sectors is non complete) and for fixed number $n$, only some of the eigenvalues $A_s(D)$, ($s = 0, 1, 2...n$) can be calculated from an nth-degree algebraic equation. We can say that eqs. (7) and (8) “remember” their polynomial solutions. It is obvious that the spectrum of $A_s(D)$, ($s = 0, 1, 2...n$) and occurrence of polynomial solutions of each of the equations (7)-(8) coincide with the eigenvalues of separation constants and the wave function after the reduction to one of the regions $\mu \in [0, 2\pi]$ or $\nu \in [0, \infty]$ for the 2d hydrogen atom.

These phenomena have been intensively discussed in the literature in the late 1980’s and called quasi-exact solvability (this term was first introduced by Turbiner and Ushveridze in [59]) and models of this type called quasi-exactly solvable systems [60, 61, 62] (see also [63] and references therein). The crucial example that stimulated the investigation of quasi-exactly solvable systems is the Hamiltonian (1) with anharmonic potential

$$V(x) = \frac{1}{2} \omega^2 x^6 + 2\beta \omega^2 x^4 + (2\beta^2 \omega^2 - 2\delta \omega - \lambda)x^2 + 2\left(\delta - \frac{1}{2}\right)\left(\delta - \frac{3}{2}\right),$$

where $\omega, \beta, \delta > 1/2$ and $\lambda$ are constants. As noticed by many authors [64, 65, 66], this system admits polynomial solutions only for special values of constant $\lambda = \omega(n + 1)$, ($n = 0, 1, 2...$)

$$\Psi(x) \approx x^{2\delta - \frac{1}{2}} e^{-\frac{2}{3}x^2 - \beta \omega x^2} P_n(x^2).$$

There are different approaches to the investigation of quasi-exactly solvable systems. In the algebraic approach formulated by Turbiner in [60] quasi-exact solvability is explained in terms of a “hidden symmetry algebra” $sl(2, R)$ $^2$. More precisely this means the following: The one-dimensional Hamiltonian (1) after suitable changes of variable $z = \xi(x)$ and “gauge transformation” $H = e^{-\alpha(z)}He^{\alpha(z)}$ can be written in the form

$$H = \sum_{a,b=0,\pm} C_{ab}J_aJ_b + \sum_{a=0,\pm} C_aJ_a$$

where the first-order differential operators $\{J_\pm, J_0\}$ satisfy the commutation relations for $sl(2, R)$ [60].

The above mentioned analysis for the 2d hydrogen atom shows that, despite the elegance of the algebraic approach, the phenomena of quasi-exactly solvability has deeper roots than can explained via the “one-dimensional” model (12). Other examples are the hydrogen atom and oscillator problems on two and three-dimensional spheres [19, 67] and two-dimensional hyperboloids [22], which generate not only hyperbolic and trigonometric but elliptic quasi-exactly solvable systems (see also [68, 56, 69, 70]). We should also mention Lamé polynomials. They come from separation of variables for the Helmholtz (also superintegrable!) or Schrödinger equation in elliptic coordinates on the two-dimensional sphere. As also determined in [37] (without showing the mechanism of this phenomena) some of the quasi-exactly solvable systems

---

$^2$This is not a hidden dynamical symmetry in the usual sense because the Hamiltonian (12) belongs to the enveloping algebra but is not a Casimir operator.
can be obtained through dimensional reduction from two and three-dimensional superintegrable models with quadratic invariants (second-order superintegrability).

A second approach, known as analytic, was formulated by Ushveridze (see for example [61, 62, 63]) and represents a one-dimensional reduction of the Niven-Stieltjes method for solving multiparameter spectral problems such as the generalized Lamé equation (or ellipsoidal equation) [33]. The solution in this method is determined by the zeros of polynomials \( P_n(x^2) \). Then the wave function (11) can be rewritten in the form

\[
\Psi(x) \approx x^{28-\frac{1}{2}} e^{-\frac{x^4}{2}} \Pi_{i=0}^{n}(x^2 - \xi_i),
\]

where the numbers \((\xi_1, \xi_2, \ldots, \xi_n)\) satisfy a system of \( n \) algebraic equations (see section 2.3). According to the oscillation theorem, the number of zeros in the physical interval \( \xi_i \in [0, \infty) \) enumerates the ground state and first \( n \) - excitations, described in terms of all zeros (complete solutions of the systems of algebraic equations and including non physical section \( \xi_i \in (-\infty, 0) \) as

\[
E = 4\delta \left[ \beta \omega + \sum_{i=1}^{n} \frac{1}{\xi_i} \right].
\]

Two natural questions occur in this approach: what is the physical meaning of the negative zeros \( \xi_i \), and why in the correct formula for the energy spectrum (14) do \( n \) zeros of the polynomial \( P_n(x^2) \) appear?

With this article we begin an investigation of second-order superintegrable systems on constant curvature spaces (Euclidean, sphere, hyperboloid and pseudo-Euclidean) based on the superintegrability and direct solutions of the Schrödinger equation. We pay special attention to non-subgroup type coordinates and prove the existence of polynomial solutions for several of these systems. We demonstrate that quasi-exact solvability is directly related with multi-separability of second-order superintegrable systems, on one hand, and with the presence of polynomial solutions for these systems on the other.

The first part of this paper is devoted to two (singular anisotropic and singular circular oscillators) from the four possible superintegrable systems in two-dimensional real Euclidean space (see for example [19]. The other two systems may be transformed (only for the discrete spectrum!) to the singular circular oscillator (for \( V_3 \)) or ordinary shifted oscillator (for \( V_4 \)) systems by the help of the Levi-Civita mapping [71], so are less fundamental for our purposes. In the second part of the paper we give some examples of superintegrable systems in three dimensions that reinforce our definitions of exact and quasi-exact solvability. In particular we exhibit a quasi-exactly solvable superintegrable system which is not at the same time exactly solvable in any separable set of coordinates. In one set of separable coordinates this provides deeper insight into an example of Ushveridze, [63], page 155, (the 10th order polynomial QES problem) and also leads to a 4th order polynomial QES problem in another separable coordinate set. In addition we indicate precisely how the eigenvalues of the symmetry operators which describe separation can be calculated from a determinantal condition. For these examples we will work with complex superintegrable systems and not address the relatively simple issue of determining the distinct real restrictions of the complex spaces. These examples greatly clarify the concepts and show how the extension to \( N \) dimensions can be achieved.
2 The singular anisotropic oscillator

Let us first consider the potential \( (k_2 > 0) \)

\[
V_1(x, y) = \frac{1}{2} \omega^2 (4x^2 + y^2) + k_1 x + \frac{k_2^2 - \frac{1}{4}}{2y^2}
\]  
(15)

(second potential on table 1.), the singular anisotropic oscillator. The Schrödinger equation has the form

\[
\left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) \Psi + \left[ 2E - \omega^2 (4x^2 + y^2) - 2k_1 x - \frac{k_2^2 - \frac{1}{4}}{y^2} \right] \Psi = 0.
\]  
(16)

For \( k_2 > 1/2 \) the singular term at \( y = 0 \) is repulsive and the motion takes place only on one of the half planes \((-\infty < x < \infty, \ y > 0)\) or \((-\infty < x < \infty, \ y < 0)\), whereas for \( 0 < k_2 < 1/2 \) in whole plane \((x, y)\). The Schrödinger equation separates in two systems: Cartesian and parabolic coordinates.

2.1 Cartesian bases

Separation of variables for eq. (16) in Cartesian coordinates leads to the two independent one-dimensional Schrödinger equations

\[
\frac{d^2 \psi_1}{dx^2} + (2\lambda_1 - 4\omega^2 x^2 - 2k_1 x) \psi_1 = 0.
\]  
(17)

\[
\frac{d^2 \psi_2}{dy^2} + \left( 2\lambda_2 - \omega^2 y^2 - k_2^2 - \frac{1}{4} \right) \psi_2 = 0.
\]  
(18)

where

\[
\Psi(x, y; k_1, \pm k_2) = \psi_1(x; k_1) \psi_2(y; \pm k_2)
\]  
(19)

and \( \lambda_1, \lambda_2 \) are Cartesian separation constants with \( \lambda_1 + \lambda_2 = E \).

Equation (18) represents the well-known linear singular oscillator system (see for instance the books [72, 73] and articles [10, 20, 74]). It is an exactly solvable problem and has been used in many applications, for example as a model in N-body problems [75], or fractional statistics and anyons [76, 77]. The complete set of orthonormalized eigenfunctions, (on 1/2) in the interval \( 0 < y < \infty \) of eq. (18), can be expressed in terms of finite confluent hypergeometric series or Laguerre polynomials

\[
\psi_{n_2}(y; \pm k_2) = \sqrt{\frac{2\omega(1\pm k_2)n_2!}{\Gamma(n_2 \pm k_2 + 1)}} y^{\frac{1}{2} \pm k_2} e^{-\frac{1}{2} \omega y^2} I_{n_2}^{1 \pm k_2} (\omega y^2)
\]  
(20)

where \( \lambda_2 = \omega(2n_2 + 1 \pm k_2) \). We assume that the positive sign at the \( k_2 \) has to be taken if \( k_2 > \frac{1}{2} \) and both the positive and the negative sign must be taken if \( 0 < k_2 < \frac{1}{2} \), so that the polynomials have finite norm. Let us also note that unlike the potential (15) the wave function
is not invariant under the replacement \( k_2 \rightarrow -k_2 \) and splits into two families of solutions that
transform to one another under this change.

The second equation (17) easily transforms to the ordinary one-dimensional oscillator problem. In terms of Hermite polynomials the orthonormal solutions (in region \(-\infty < x < \infty\)) are

\[
\psi_{n1}(x; k_1) = \left( \frac{2\omega}{\pi} \right)^{1/4} \frac{e^{-\omega z^2}}{\sqrt{2^{n_1}n_1!}} H_{n_1}(\sqrt{2\omega}z), \quad z = x + \frac{k_1}{4\omega^2},
\]

where \( \lambda_1 = \omega(2n_1 + 1) - \frac{k_1^2}{8\omega^2} \). Thus the complete energy spectrum is

\[
E = \lambda_1 + \lambda_2 = \omega[2n + 2 \pm k_2] - \frac{k_1^2}{8\omega^2}, \quad n = n_1 + n_2 = 0, 1, 2, ...
\]

and the degree of degeneracy for fixed principal quantum number \( n \) is \((n + 1)\). Finally note that the separation of variables in Cartesian coordinates leads to two \textbf{exactly solvable} one-dimensional Schrödinger equations and the complete wave function may be constructed with the help of formulas (20), (21) and (19).

\section*{2.2 Parabolic bases}

\subsection*{1.2.1. Separation of variables.}
Parabolic coordinates \( \xi \) and \( \eta \) are connected with the Cartesian \( x \) and \( y \) by

\[
x = \frac{1}{2}(\xi^2 - \eta^2), \quad y = \xi\eta, \quad \xi \in \mathbb{R}, \eta > 0.
\]

The Laplacian and the two-dimensional volume element are given by

\[
\Delta = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} = \frac{1}{\xi^2 + \eta^2} \left( \frac{\partial^2}{\partial \xi^2} + \frac{\partial^2}{\partial \eta^2} \right), \quad dv = dx\,dy = (\xi^2 + \eta^2)d\xi\,d\eta.
\]

The Schrödinger equation in parabolic coordinates (23) is

\[
\frac{1}{\xi^2 + \eta^2} \left( \frac{\partial^2 \Psi}{\partial \xi^2} + \frac{\partial^2 \Psi}{\partial \eta^2} \right) + \left( 2E - \omega^2(\xi^2 - \xi^2\eta^2 + \eta^4) - k_1(\xi^2 - \eta^2) - \frac{k_2^2}{\xi^2\eta^2} \right) \Psi = 0.
\]

Upon substituting

\[
\Psi(\xi, \eta) = X(\xi)Y(\eta)
\]

and introducing the parabolic separation constant \( \lambda \), the equation (25) splits into two ordinary differential equations:

\[
\frac{d^2X}{d\xi^2} + \left( 2E\xi^2 - \omega^2\xi^6 - k_1\xi^4 - \frac{k_2^2}{\xi^2} - \frac{1}{\xi^4} \right) X = -\lambda X, \quad \lambda \in \mathbb{R},
\]

\[
\frac{d^2Y}{d\eta^2} + \left( 2E\eta^2 - \omega^2\eta^6 + k_1\eta^4 - \frac{k_2^2}{\eta^2} - \frac{1}{\eta^4} \right) Y = +\lambda Y.
\]
Equations (26) and (27) are transformed into one another by change $\xi \leftrightarrow i\eta$. We have

$$\Psi(\xi, \eta; E, \lambda) = C(E, \lambda)Z(\xi; E, \lambda)Z(i\eta; E, \lambda)$$

(28)

where $C(E, \lambda)$ is the normalization constant determined by the condition

$$\int_0^\infty d\eta \int_{-\infty}^\infty d\xi (\xi^2 + \eta^2)|\Psi(\xi, \eta; E, \lambda)|^2 = 1$$

(29)

and the function $Z(\mu; E, \lambda)$ is a solution of the equation

$$\left[-\frac{d^2}{d\mu^2} + \left(\omega^2 \mu^6 + k_1 \mu^4 - 2E \mu^2 + \frac{k_2^2 - \frac{1}{4}}{\mu^2}\right)\right]Z(\mu; E, \lambda) = \lambda Z(\mu; E, \lambda).$$

(30)

Thus, at $\mu \in (-\infty, \infty)$ we have eq. (26) and at $\mu \in [0, i\infty)$ - the eq. (27). Note that in the complex $\mu$ domain the “physical” region is just the two lines $\text{Im} \mu = 0$ and $\text{Re} \mu = 0, \text{Im} \mu > 0$. Our task is to find the solutions of eq. (30) that are regular and decreasing as $\mu \to \pm \infty$ and $\mu \to i\infty$.

1.2.2. Recurrence relations.

Consider now the equation (30). To solve it we make the substitution

$$Z(\mu; E, \lambda) = \exp\left(-\frac{\omega}{4} \mu^4 - \frac{k_1}{4\omega} \mu^2\right) \mu^{\frac{1}{2} + k_2} \psi(\mu; E, \lambda),$$

(31)

and obtain the differential equation

$$\frac{d^2\psi}{d\mu^2} + \left[\frac{2(\frac{1}{2} \pm k_2)}{\mu} - 2\omega \mu \left(\frac{\mu^2 + k_1}{2\omega^2}\right)\right] \frac{d\psi}{d\mu} + \left[2\tilde{E} \mu^2 + \tilde{\lambda}\right] \psi = 0$$

(32)

where

$$\tilde{E} = E + \frac{k_1^2}{8\omega^2} - \omega(2 \pm k_2), \quad \tilde{\lambda} = \lambda - \frac{k_1}{\omega}(1 \pm k_2).$$

(33)

Passing to a new variable $z = \mu^2$ in eq. (32), we have

$$z \frac{d^2\psi}{dz^2} + \left[(1 \pm k_2) - \omega z \left(z + \frac{k_1}{2\omega^2}\right)\right] \frac{d\psi}{dz} + \left[\frac{1}{2}\tilde{E} z + \frac{1}{4}\tilde{\lambda}\right] \psi = 0.$$  

(34)

We express the wave function $\psi(z)$ in the form

$$\psi(z; E, \lambda) = \sum_{s=0}^{\infty} A_s(E, \lambda) z^s.$$  

(35)

The substitution (35) in eq. (34) leads to the following three-term recurrence relation for the expansion coefficients $A_s \equiv A_s(E, \lambda)$,

$$(s + 1)(s + 1 \pm k_2)A_{s+1} + \frac{1}{4} \left[\lambda - \frac{k_1}{\omega}(2s + 1 \pm k_2)\right]A_s +\frac{1}{2} \left[E + \frac{k_1}{8\omega^2} - \omega(2s \pm k_2)\right]A_{s-1} = 0,$$

(36)
with the initial conditions $A_{-1} = 0$ and $A_0 = 1$.

As shown in the Appendix, the asymptotic behavior of the expansion coefficients $A_s \equiv A_s(E, \lambda)$ for large $s$ is $A_s \sim \sqrt{s} e^{-\sqrt{s}}$, depending on whether $s$ is even or odd, and

$$
\psi(z) \sim \sum \frac{\sqrt{\xi_\pm(\sqrt{\omega} z)^s}}{\sqrt{s!}}.
$$

(37)

Then we have for $z > 0$ [the case of eq. (26)]

$$
\sum \frac{\sqrt{\xi_\pm(\sqrt{\omega} z)^s}}{\sqrt{s!}} > \sqrt{\sum \frac{\xi_\pm(\omega z^2)^s}{s!}} = \xi_\pm \cosh \left( \frac{\omega z^2}{2} \right) + \xi_\mp \sinh \left( \frac{\omega z^2}{2} \right).
$$

(38)

This function does not belong to the Hilbert space. If $k_1 > 0$ then we must make the replacements $b_s \rightarrow -b_s$ and $\xi_s \rightarrow -\xi_s$. This has the effect of replacing $z$ by $-z$ in (37). Now the asymptotic solution is oscillatory. However, for $z < 0$ [the case of eq. (27)] the solution doesn’t belong to the Hilbert space. The solution we have found is the minimal solution of the three-term recurrence relations. There is a linearly independent solution, but the coefficients grow more rapidly than the minimal solution coefficients.

1.2.4. Energy spectrum and separation constant.

The function $Z(\mu)$ cannot converge simultaneously at large $\mu$ for real and imaginary $\mu$ and therefore the series (35) should be truncated in order to obtain convergence. The condition for series (35) to be truncated results in the energy spectrum (22) where now the coefficients $A_s \equiv A^s(k_1, \pm k_2)$ satisfy the relation

$$
(s + 1)(s + 1 \pm k_2)A_{s+1} + \beta_s A_s + \omega(n + 1 - s)A_{s-1} = 0, \quad \beta_s = \frac{\lambda}{4} - \frac{k_1}{4}\omega(2s + 1 \pm k_2).
$$

(39)

The three-term recurrence relations (39) represent a homogeneous system of $n + 1$ algebraic equations for $n + 1$ coefficients \{A_0, A_1, A_2, ... A_n\}. The requirement for the existence of a non-trivial solution leads to a vanishing of the determinant

$$
D_n(\lambda) = \begin{vmatrix}
\beta_0 & 1 \pm k_2 & \cdot & \cdot & \cdot \\
\omega n & \beta_1 & 2(\pm k_2) & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot \\
2\omega & \beta_{n-1} & n(n \pm k_2) & \omega & \beta_n \\
\cdot & \cdot & \cdot & \cdot & \cdot
\end{vmatrix} = 0.
$$

(40)

The roots of the corresponding algebraic equation give us the \((n+1)\) eigenvalues of the parabolic separation constant $\lambda_n(k_1, \pm k_2)$. It is known that all roots for such determinants are real and distinct \cite{78}. Thus all values of the separation constant are real and can be enumerated with the help of the integer $q$, namely the values are $\lambda_n(k_1, \pm k_2) \rightarrow \lambda_{nq}(k_1, \pm k_2)$, where $0 \leq q \leq n$. The degeneracy for the $n$ - energy state, as in the Cartesian case, equals $n + 1$.

Note that eq. (40) is invariant under the simultaneous transformation $k_1 \rightarrow -k_1$ and $\lambda \rightarrow -\lambda$. Thus if one of the $\lambda = \lambda_n(k_1, \pm k_2)$ is a root of eq. (40), then $\lambda = -\lambda_n(-k_1, \pm k_2)$ is also a root of the same equation. We see that for the odd energy state \((n\text{-odd})\) the range of $\lambda_{nq}(k_1, \pm k_2)$ splits into two subsets $\lambda_{nq}^{(1)}(k_1, \pm k_2)$ and $\lambda_{nq}^{(2)}(k_1, \pm k_2)$ connected by the relation $\lambda_{nq}^{(1)}(k_1, \pm k_2) \leftrightarrow \lambda_{nq}^{(2)}(k_1, \pm k_2)$
\[-\lambda_{nq}^{(2)}(-k_1, \pm k_2). \text{ For } n\text{-even, there exists the additional root } \lambda_{nq}(k_1, \pm k_2) = -\lambda_{nq}(-k_1, \pm k_2), \text{ which equals zero when } k_1 = 0.\]

1.2.5. Wave functions.

We will term the polynomial solutions of eq.(34), or eq.(32), as \(Mk_{nq}(z; k_1, \pm k_2)\), and the function (31) as \(Ta_{nq}(z; k_1, \pm k_2)\). Then the physical admissible solutions of eq. (34) have the form

\[Mk_{nq}(z; k_1, \pm k_2) \equiv \psi(z; E, \lambda) = \sum_{s=0}^n A_nq(k_1, \pm k_2) z^s, \tag{41}\]

and the corresponding solution of eq. (31) is

\[Ta_{nq}(\mu; k_1, \pm k_2) = \exp\left(-\frac{\omega}{4} \mu^4 - \frac{k_1}{4\omega} \mu^2 \right) \mu^{1 \pm k_2} Mk_{nq}(\mu^2; k_1, \pm k_2). \tag{42}\]

Observe that parabolic wave functions (and also Cartesian wave functions) split into two classes and transform to each other via \(k_2 \rightarrow -k_2\). In the case \(k_2 = 0\) (when the centrifugal term disappears), the solution (42) becomes an even and odd parity wave function under the exchange \(\mu \rightarrow -\mu\).

It is known that there exists a direct connection between the quantum numbers \(q\) and numbers of zeros of the polynomial (41) and, therefore, the eigenvalues of the separation constant \(\lambda_{nq}(k_1, \pm k_2)\) may be ordered by the numbers of nodes of the wave function \(Ta_{nq}(\mu; k_1, \pm k_2)\). Indeed we will see that these are orthogonal polynomials, hence [50], all the \(n\) - zeros of the \(Mk_{nq}(z; k_1, \pm k_2)\) are situated on the real axis \(-\infty < z < \infty\), and all zeros have multiplicity one. Assume that the separation constants \(\lambda_{nq}(k_1, \pm k_2)\) are enumerated in ascending order, i.e.

\[\lambda_{n0}(k_1, \pm k_2) < \lambda_{n1}(k_1, \pm k_2) < \ldots < \lambda_{n,n-1}(k_1, \pm k_2) < \lambda_{n,n}(k_1, \pm k_2). \tag{43}\]

Then according to the oscillation theorem [79], the quantum number \(q\) also enumerates the zeros of polynomials \(Mk_{nq}(z; k_1, \pm k_2)\) in the region \(z > 0\), or the real axis of \(\mu\). Let us now introduce two quantum numbers \(q_1\) and \(q_2\), which determine the zeros of polynomials \(Mk_{nq}(z; k_1, \pm k_2)\) for \(z > 0\) and \(z < 0\), correspondingly. Then \(q_1 + q_2 = n\), and

\[\lambda_{nq_1}(k_1, \pm k_2) = -\lambda_{nq_2}(-k_1, \pm k_2). \tag{44}\]

For \(\mu = \xi\) the function (42) gives the solution of equation (26), and for \(\mu = i\eta\) the solution of equation (27). Thus the parabolic wave function (28) can be written in the following way

\[\Psi_{nq_1q_2}(\xi, \eta; k_1, \pm k_2) = C_{nq_1q_2}(k_1, \pm k_2) Ta_{nq_1}(\xi; k_1, \pm k_2) Ta_{nq_2}(i\eta; k_1, \pm k_2). \tag{45}\]

1.2.6. Orthogonality relations and normalization constant.

The wave functions (45) as eigenfunctions of Hamiltonians are orthogonal for quantum number \(n\), or for \(n \neq n'\)

\[\int_0^\infty d\eta \int_0^\infty d\xi (\xi^2 + \eta^2) \Psi_{n'q_1q_2}(\xi, \eta; k_1, \pm k_2) \Psi_{nq_1q_2}^*(\xi, \eta; k_1, \pm k_2) = 0. \tag{46}\]
Because the energy spectrum is degenerate there exist additional orthogonality relations for quantum number \( q \). Using the equations (26) and (27) it is easy to prove that for \( q_1 \neq q_1' \) and \( q_2 \neq q_2' \)

\[
\int_{-\infty}^{\infty} d\xi T_{n,q_1'}(\xi; k_1, \pm k_2) T_{n,q_1}(\xi; k_1, \pm k_2) = \int_{0}^{\infty} d\eta T_{n,q_2'}(i\eta; k_1, \pm k_2) T_{n,q_2}(i\eta; k_1, \pm k_2) = 0, \tag{47}
\]

Thus we have for \( q \neq q' \)

\[
\int_{0}^{\infty} d\eta \int_{-\infty}^{\infty} d\xi (\xi^2 + \eta^2) \Psi^{*}_{n,q_1'}(\xi, \eta; k_1, \pm k_2) \Psi_{n,q_2'}(\xi, \eta; k_1, \pm k_2) = 0. \tag{48}
\]

Let us now calculate the normalization constant \( C_{n,q_1q_2}(k_1, \pm k_2) \). From the explicit form of the wave function \( \Psi^{*}_{n,q_1q_2}(\xi, \eta; k_1, \pm k_2) \) and the normalization condition (29), it follows that

\[
\frac{1}{8} |C_{n,q_1q_2}(k_1, \pm k_2)|^2 \sum_{n,s',t',t=0}^{n} (-1)^{t+t'} A_n^a(k_1, \pm k_2) A_{n'}^b(k_1, \pm k_2)
\]

\[
\times A_n^a(k_1, \pm k_2) A_{n'}^b(k_1, \pm k_2) \left\{ F_{t,t'}^{-1/4} F_{t',t}^{-1/4} + F_{t,t'}^{+1/4} F_{t',t}^{-1/4} \right\} = 1 \tag{49}
\]

where

\[
F_{t,t'}^{\pm 1/4} = \sum_{m=0}^{\infty} \frac{\Gamma(m+t'+k_2+1/2)}{m!} \left( \frac{k_1}{2\omega} \right)^m. \tag{50}
\]

### 2.3 Niven approach

Let us express solutions of the Schrödinger equation (16) in the following form [19]

\[
\Psi(x, y) = e^{-\omega x + \frac{k_1}{8}\omega^2} y^{k_2} \Phi(x, y). \tag{51}
\]

From eqs. (20), (21) and (31) follows that the function \( \Phi(x, y) \) is a polynomial (product of two polynomials) in terms of the variables \((x, y^2)\) in Cartesian coordinates and \((\xi^2, \eta^2)\) for parabolic ones. It satisfies the equation

\[
\mathcal{R}\Phi(x, y) = -2E\Phi(x, y), \tag{52}
\]

where the operator \( \mathcal{R} \) is

\[
\mathcal{R} = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \left[ \frac{1 \pm 2k_2}{y} - 2\omega y \right] \frac{\partial}{\partial y} - 4\omega \left[ x + \frac{k_1}{4\omega^2} \right] \frac{\partial}{\partial x} - \omega(2 \pm k_2) + \frac{k_1^2}{8\omega^2}. \tag{53}
\]

Taking into account that

\[
M k_{nq}(z; k_1, \pm k_2) = \sum_{n=0}^{n} A_{n,q}^a(k_1, \pm k_2) z^n = \Pi_{\ell=1}^{n}(z - \alpha_{\ell}), \tag{54}
\]

where \( \alpha_{\ell}, \ell = 1, 2, \ldots, n \) are zeros of polynomials \( M k_{nq}(z) \) on the real axis \(-\infty < z < \infty\), and that in parabolic coordinates

\[
\frac{y^2}{\alpha} + 2x - \alpha = \frac{(\xi^2 - \alpha)(\eta^2 + \alpha)}{\alpha}, \tag{55}
\]

\[
12
\]
we can choose a solution of eq. (52) in the form

$$\Phi(x, y) = Mk_{nq_1}(\xi^2; k_1, \pm k_2) Mk_{nq_2}(-\eta^2; k_1, \pm k_2) \cong \Pi_{\ell=1}^{n} \left( \frac{\eta^2}{\alpha_\ell} + 2x - \alpha_\ell \right).$$  \hspace{1cm} (56)

Then from (52) it follows that the zeros $\alpha_\ell$ must satisfy the systems of $n$ - algebraic equations

$$\sum_{m \neq \ell}^{n} \frac{2}{\alpha_\ell - \alpha_m} + \frac{(1 \pm k_2)}{\alpha_\ell} - \omega \alpha_\ell = \frac{k_1}{2\omega}, \quad \ell = 1, 2, \ldots, n,$$  \hspace{1cm} (57)

and for the energy spectrum we again have a formula (22). The system of algebraic equations (57) contains $n$ - sets of solutions (zeros) $(\alpha_1^{(q)}, \alpha_2^{(q)}, \ldots, \alpha_n^{(q)}), q = 1, 2, \ldots n$ and all zeros are real. The positive zeros $\alpha_\ell > 0$ define the nodes of wave functions for equation (26), whereas negative zeros $\alpha_\ell < 0$ define the nodes of wave functions for equation (27).

The eigenvalues of the parabolic separation constant can be calculated in the same way via the operator equation $\Delta \Phi(x, y) = \lambda \Phi(x, y)$ (see for details [19]). A more elegant way is to use directly the differential equation (34) [63]. We first rewrites the eq. (34) in the form

$$\left\{ 4z \frac{d^2}{dz^2} + \frac{4}{(1 \pm k_2) - \omega z} \left( z + \frac{k_1}{2\omega^2} \right) \frac{d}{dz} + \left[ 4n\omega z - \frac{k_1}{\omega}(1 \pm k_2) \right] \right\} Mk_{nq}(z; k_1, \pm k_2) = \lambda Mk_{nq}(z; k_1, \pm k_2).$$  \hspace{1cm} (58)

Putting the wave function $Mk_{nq}(z; k_1, \pm k_2)$ in the form of (54), we arrive at the following result

$$\lambda_{nq}(k_1, \pm k_2) = 4(1 \pm k_2) \left[ \frac{k_1}{4\omega} + \sum_{\ell=1}^{n} \frac{1}{\alpha_\ell^{(q)}} \right],$$

(59)

(in case of $n = 0$ the sum must be eliminated) where the quantum number $q = 1, 2, \ldots n$ labels the eigenvalue of the parabolic separation constant.

3 The singular circular oscillator

The potential of the singular circular oscillator is $(k_1, k_2 > 0)$

$$V_2(x, y) = \frac{1}{2} \omega^2 (x^2 + y^2) + \frac{1}{2} \left( \frac{k_1^2 - \frac{1}{4}}{x^2} + \frac{k_2^2 - \frac{1}{4}}{y^2} \right).$$  \hspace{1cm} (60)

The corresponding Schrödinger equation separates in three different orthogonal coordinate systems: Cartesian, polar and elliptical coordinates.

3.1 Cartesian bases

From the asymptotic ansatz

$$\Psi(x, y) = x^{\frac{k_1}{2} \pm k_1} y^{\frac{k_2}{2} \pm k_2} \exp[-\omega(x^2 + y^2)] X(x)X(y)$$

(61)
we obtain two independent and identical separation equations
\[
\left[ \frac{\partial^2}{\partial x_i^2} + \left( -2\omega + \frac{1 \pm 2k_i}{x_i^2} \right) x \frac{\partial}{\partial x_i} - (1 \pm 2k_i)\omega \right] X(x_i) = 2\lambda_i X(x_i), \quad i = 1, 2 \tag{62}
\]
where \( x_1 = x, x_2 = y \) and \( \lambda_1 + \lambda_2 = -E \). As in the case of the singular anisotropic oscillator we assume that the positive sign of \( k_i \) has to be taken if \( k_i > \frac{1}{2} \) and both the positive and the negative sign must be taken if \( 0 < k_i < \frac{1}{2} \).

The last equation is just that for confluent hypergeometric functions. The quantization rule gives
\[
\lambda_i = -\omega(2n_i \pm k_i + 1), \quad n_i = 0, 1, 2, \ldots \tag{63}
\]
and the solution of eq. (62) in terms of Laguerre polynomials is \( X(x_i) = L_{n_i}^{\pm k_i}(\omega x_i^2) \). Thus the corresponding set of orthonormal eigenfunctions which are normalized in quadrant \( x > 0, y > 0 \) (on 1/4) is
\[
\Psi_{n_1,n_2}^{(\pm k_1,\pm k_2)}(x,y) = C_{n_1,n_2}^{(\pm k_1,\pm k_2)}(x) \frac{\sqrt{\omega}^{\pm k_1 \pm k_2}}{\Gamma(n_1 \pm k_1 + 1)\Gamma(n_2 \pm k_2 + 1)} L_n^{\pm k_1}(\omega x^2) L_m^{\pm k_2}(\omega y^2) \tag{64}
\]
where
\[
C_{n_1,n_2}^{(\pm k_1,\pm k_2)} = \frac{\omega^{\pm k_1 \pm k_2} n_1! n_2!}{\Gamma(n_1 \pm k_1 + 1)\Gamma(n_2 \pm k_2 + 1)}. \tag{65}
\]
From (63) we have
\[
E_n = \omega(2n + 2 \pm k_1 \pm k_2), \tag{66}
\]
where \( n = n_1 + n_2 = 0, 1, 2, \ldots \) is the principal quantum number and the degree of degeneracy is \( n + 1 \).

### 3.2 Polar bases

Separation of variables in the Schrödinger equation for the potential (61) in polar coordinates
\[
x = r \cos \phi, \quad y = r \sin \phi, \quad 0 \leq r < \infty, \quad 0 \leq \phi < 2\pi \tag{67}
\]
gives us the orthonormal solution in polynomial form
\[
\Psi_{n_r,m}^{(\pm k_1,\pm k_2)}(r, \phi) = \sqrt{\frac{2\omega n_r!}{\Gamma(n_r + 2m \pm k_1 \pm k_2 + 2)}} (\sqrt{\omega} r)^{(2m \pm k_1 \pm k_2 + 1)} e^{-\frac{r^2}{2}} L_n^{2q \pm k_1 \pm k_2 + 1}(\omega r^2) \Phi_{m}^{(\pm k_1,\pm k_2)}(\phi), \quad n_r, m = 0, 1, 2, \ldots \tag{68}
\]
\[
\Phi_{m}^{(\pm k_1,\pm k_2)}(\phi) = \sqrt{\frac{(2m \pm k_1 \pm k_2 + 1) q! \Gamma(q \pm k_1 \pm k_2 + 1)}{2 \Gamma(m \pm k_2 + 1) \Gamma(m \pm k_1 + 1)}} \times (\cos \phi)^{1/2 \pm k_1} (\sin \phi)^{1/2 \pm k_2} P_{m}^{(\pm k_2 \pm k_1)}(\cos 2\phi) \tag{69}
\]
where \( P_{m}^{(\alpha,\beta)}(x) \) is a Jacobi polynomial and \( E = \omega(2n \pm k_1 \pm k_2 + 2) \), with \( n = n_r + m \) and with the same degree of degeneracy \( (n + 1) \).

Thus the quantum system (60) is exactly solvable in the Cartesian and polar systems of coordinates.
3.3 Elliptic bases

3.3.1. Separation of variables.

Elliptic coordinates \((\nu, \mu)\) connect with Cartesian ones by \(0 \leq \nu < \infty, \ 0 \leq \mu < 2\pi\)

\[
x = \frac{D}{2} \cosh \nu \cos \mu, \quad y = \frac{D}{2} \sinh \nu \sin \mu, \tag{70}
\]

where \(D\) is the inter-focal distance. The Laplacian and volume element are

\[
\Delta = \frac{8}{D^2} \left( \frac{\partial^2}{\partial \nu^2} + \frac{\partial^2}{\partial \mu^2} \right), \quad dV = \frac{D^2}{8} (\cosh 2\nu - \cos 2\mu) d\nu d\mu. \tag{71}
\]

The Schrödinger equation with (60) can be rewritten as

\[
\frac{\partial^2 \psi}{\partial \nu^2} + \frac{\partial^2 \psi}{\partial \mu^2} + \left\{ \frac{D^2 E}{4} (\cosh 2\nu - \cos 2\mu) - \frac{D^4 \omega^2}{64} (\cosh^2 2\nu - \cos^2 2\mu) - \left[ \frac{(k_1^2 - \frac{1}{4})}{\cos^2 \mu} + \frac{(k_2^2 - \frac{1}{4})}{\sin^2 \mu} \right] \right. - \left[ \frac{(k_1^2 - \frac{1}{4})}{\sin^2 \nu} + \frac{(k_2^2 - \frac{1}{4})}{\cosh^2 \nu} \right] \right\} \psi = 0, \tag{72}
\]

and after the separation ansatz

\[
\psi(\nu, \mu; D^2) = X(\nu; D^2)Y(\mu; D^2) \tag{73}
\]

transforms to two ordinary differential equations

\[
\frac{d^2 X}{d\nu^2} + \left[ \frac{D^2 E}{4} \cosh 2\nu - \frac{D^4 \omega^2}{64} \cosh^2 2\nu - \frac{k_1^2 - \frac{1}{4}}{\sin^2 \nu} + \frac{k_1^2 - \frac{1}{4}}{\cosh^2 \nu} \right] X = -\lambda (D^2) X, \tag{74}
\]

\[
\frac{d^2 Y}{d\mu^2} - \left[ \frac{D^2 E}{4} \cos 2\mu - \frac{D^4 \omega^2}{64} \cos^2 2\mu + \frac{k_2^2 - \frac{1}{4}}{\cos^2 \mu} + \frac{k_2^2 - \frac{1}{4}}{\sin^2 \mu} \right] Y = +\lambda (D^2) Y, \tag{75}
\]

where \(\lambda\) is the elliptic separation constant. These equations can be written in the unit form

\[
\frac{d^2 Z(\zeta)}{d\zeta^2} + \left[ \frac{D^4 \omega^2}{64} \cos^2 2\zeta - \frac{D^2 E}{4} \cosh 2\zeta - \frac{k_1^2 - \frac{1}{4}}{\cos^2 \zeta} - \frac{k_2^2 - \frac{1}{4}}{\sin^2 \zeta} \right] Z(\zeta) = \lambda (D^2) Z(\zeta) \tag{76}
\]

where at \(\zeta \in [0, 2\pi]\) we have the equation (75) but at \(\zeta \in [0, \infty)\) - equation (74). In other words, in the complex \(\zeta\) plane the “physical regions” are only the shaded domains on the two lines \(\text{Im } \zeta = 0\) and \(\text{Re } \zeta = 0\).

For \(k_{1,2} > \frac{1}{2}\) the centrifugal barrier is repulsive and motion takes place in only one of the quadrants, as \(\zeta \in [0, \pi/2]\), whereas for \(0 < k_{1,2} < \frac{1}{2}\) it takes place in the whole region \(\zeta \in [0, 2\pi]\). For the particular case \(k_1 = k_2 = \frac{1}{2}\) the equation (76) transforms to the problem of the ordinary two dimensional oscillator and has been investigated in detail in the paper [69]. In this article we have shown that the solution of eq. (76) (for \(k_1 = k_2 = 1/2\)) is described by Ince polynomials [80].

In the case where \(k_1\) and \(k_2\) are integers, eqs. (74) and (75) coincide with those that have been found via separation of variables in the Schrödinger equation for the four dimensional isotropic oscillator in spheroidal coordinates [70].
3.3.2. Recurrence relations.
Let us now consider the equation (76). First, introducing the function $W(\zeta; D^2)$ according to
\[ Z(\zeta; D^2) = \exp \left[ -\frac{D^2 \omega}{16} \cos 2\zeta \right] W(\zeta; D^2), \] (77)
we have the equation
\[ \frac{d^2 W}{d\zeta^2} + \frac{D^2 \omega}{4} \sin 2\zeta \frac{dW}{d\zeta} + \left[ \frac{D^2 \omega}{4} \cos 2\zeta - \frac{D^2 E}{2} \cos^2 \zeta - \frac{k_1^2 - \frac{1}{4}}{\cos^2 \zeta} - \frac{k_2^2 - \frac{1}{4}}{\sin^2 \zeta} - \lambda \right] W = 0. \] (78)
For $k_1 = k_2 = 1/2$ this is the Ince equation, [50].
Next the substitution
\[ W(\zeta; D^2) = (\sin \zeta)^{1 \pm k_1} (\cos \zeta)^{1 \pm k_1} U(\zeta; D^2) \] (79)
yields the equation
\[ \frac{d^2 U}{d\zeta^2} + [(1 \pm 2k_2) \cot \zeta - (1 \pm 2k_1) \tan \zeta + \frac{D^2 \omega}{4} \sin 2\zeta] \frac{dU}{d\zeta} + [p \cos^2 \zeta - \tilde{\lambda}] U = 0, \] (80)
where
\[ p = \frac{D^2}{2} [\omega(2 \pm k_1 \pm k_2) - E], \quad \tilde{\lambda} = \lambda + \frac{D^2 \omega}{2} (1 \pm k_1) + (1 \pm k_1 \pm k_2)^2 - \frac{D^2 E}{4} - \frac{D^4 \omega^2}{64}. \] (81)
Passing to a new variable $t = \cos^2 \zeta$ we find
\[ t(1 - t) \frac{d^2 U}{dt^2} + \left\{ (1 \pm k_1)(1 - t) - (1 \pm k_2)t + \frac{D^2 \omega}{4} t(t - 1) \right\} \frac{dU}{dt} + \frac{1}{4} [pt - \tilde{\lambda}] U = 0. \] (82)
Finally, looking for the solution of the last equation in the form
\[ U(t; D^2) = \sum_{s=0}^{\infty} A_s(D^2) t^s, \] (83)
for coefficients $A_s(D^2)$ we have the three-term recurrence relation
\[ (s + 1)(s + 1 \pm k_1) A_{s+1} - \left[ s(s + 1 \pm k_1 \pm k_2) + \frac{D^2 \omega}{4} s + \frac{\tilde{\lambda}}{4} \right] A_s + \frac{1}{4} [p + D^2 \omega (s - 1)] A_{s-1} = 0, \] (84)
with $A_{-1} = 0$ and initial condition $A_0 = 1$.

3.3.3. Energy spectrum and separation constant.
In analogy with our asymptotic solution of the recurrence relation for the singular anisotropic operator in the parabolic basis we use continued fractions. For the minimal solution of the recurrence relations we find for $s^{-1} \ll 1$
\[ \frac{A_{s+1}}{A_s} \sim \frac{D^2 \omega}{4s} \left( 1 + O \left( \frac{1}{\sqrt{s}} \right) \right). \] (85)
Thus we have

$$A_s \sim \left(\frac{D^2 \omega}{4}\right)^s, $$

and

$$U(\cos \zeta) \sim \sum \frac{(D^2 \omega)^k}{k!} \cos^{2k} \zeta \sim \exp\left(\frac{D^2 \omega}{8} \cos 2\zeta\right). \quad (86)$$

Therefore we see that for this case the function $Z(\cos \zeta; D^2)$ as $\zeta \to \infty$ is not normalizable. There is a linearly independent solution of the recurrence relations, but the coefficients grow even faster. Hence it follows that the series (83) should be truncated. The condition that the series (83) be truncated gives us well known formulas for the energy spectrum (66) and reduces the solution to polynomials:

$$U_{[(\pm k_1, \pm k_2)]} (t; D^2) = \sum_{s=0}^{n} A_s(\pm k_1, \pm k_2)(D^2)t^s, \quad (87)$$

where now the coefficients $A_s = A_s(\pm k_1, \pm k_2)(D^2)$ satisfy the following three-term recurrent relations

$$(s + 1)(s + 1 \pm k_1)A_{s+1} + \beta_s A_s - \frac{D^2 \omega}{4}(n - s + 1)A_{s-1} = 0, \quad s = 0, 1, \ldots n \quad (88)$$

with

$$\beta_s = -\frac{1}{4} \left[(2s + 1 \pm k_1 \pm k_2)^2 + \frac{D^2 \omega}{2}(2s - n + 4 \pm 4k_1) - \frac{D^2 \omega}{4}(2 \pm k_1 \pm k_2) - \frac{D^4 \omega^2}{64} + \lambda(D^2)\right] \quad (89)$$

and $A_{-1} = A_{n+1} = 0$.

The recurrence relations (88) become a system of $(n + 1)$ linear homogeneous equations for the coefficients $A_s$. Equating the corresponding determinant to zero

$$D_n(\lambda) = \begin{vmatrix}
\beta_0 & (1 \pm k_1) & \cdot & \cdot & \cdot \\
-\frac{D^2 \omega}{4}n & \beta_1 & 2(2 \pm k_1) & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot \\
-\frac{D^2 \omega}{2} & \beta_{n-1} & n(n \pm k_1) & \cdot & \cdot \\
-\frac{D^4 \omega^2}{4} & \beta_n & & & \\
\end{vmatrix} = 0 \quad (90)$$

leads to the algebraic equation of degree $(n + 1)$ which determines the eigenvalues of the elliptic separation constant $\lambda_{nq}^{(\pm k_1, \pm k_2)}(D^2)$. The quantum number $q = 0, 1, 2, \ldots n$ labels the $(n + 1)$ roots of eq. (90) and therefore the degree of degeneracy, as in the polar and Cartesian cases, for the $n$-th energy state is $n + 1$. It is also known that the corresponding enumeration of the quantum number $q$ defines the numbers of zeros of the polynomial (87), which has exactly $n$ zeros situated in the open interval $0 < t < \infty$, and therefore, the elliptic separation constant $\lambda_{nq}^{(\pm k_1, \pm k_2)}(D^2)$ may be ordered also by the numbers of the nodes of the eigenfunction of equation (76).

3.3.5. Wave functions.
The condition of finiteness of the solution of eq. (78) allows the following polynomials:

\[ I_{nq}^{(\pm k_1, \pm k_2)}(\zeta; D^2) = (\sin \zeta)^{\frac{1}{2} \pm k_2} (\cos \zeta)^{\frac{1}{2} \pm k_1} \sum_{s=0}^{n} A_s^{(\pm k_1, \pm k_2)}(D^2)(\cos \zeta)^{2s}, \]

(91)

while the corresponding solution of eq. (76) is

\[ Z_{nq}^{(\pm k_1, \pm k_2)}(\zeta; D^2) = e^{-\frac{D^2}{4} \cos 2\zeta} I_{nq}^{(\pm k_1, \pm k_2)}(\zeta; D^2). \]

(92)

We will denote the polynomials \( I_{nq}^{(\pm k_1, \pm k_2)}(\zeta; D^2) \) as associated Ince polynomials. In the case of \( k_1 = k_2 = 1/2 \) these polynomials transform to the four types of ordinary Ince polynomials, which are even or odd with respect to the changes \( \zeta \to -\zeta \) and \( \zeta \to \zeta + \pi \) [80, 69].

At \( \zeta = \mu \) the wave functions (92) give us the solution of the angular equation (75), and for \( \zeta = i\nu \) the solution of the radial equation (74). For each of the wave functions, radial or angular, there corresponds a definite number of zeros which can be represented by two quantum numbers \( q_1 \) and \( q_2 \), obeying the condition \( q_1 + q_2 = n \). Then the complete elliptic wave function (73) may be written as

\[ \Psi_{nq_1q_2}^{(\pm k_1, \pm k_2)}(\nu, \mu; D^2) = C_{nq_1q_2}^{(\pm k_1, \pm k_2)(\mu; D^2)} Z_{nq_1}^{(\pm k_1, \pm k_2)}(\mu; D^2) Z_{nq_2}^{(\pm k_1, \pm k_2)}(i\nu; D^2), \]

(93)

where \( C_{nq_1q_2}^{(\pm k_1, \pm k_2)(\mu; D^2)} \) is the normalization constant. It could be calculated from the condition

\[ \frac{D^2}{4} \int_0^{\infty} d\nu \int_0^{\pi/2} d\mu (\cosh^2 \nu - \cos^2 \mu) \Psi_{nq_1q_2}^{(\pm k_1, \pm k_2)*}(\nu, \mu; D^2) \Psi_{nq_1q_2}^{(\pm k_1, \pm k_2)}(\nu, \mu; D^2) = \frac{1}{4}. \]

(94)

3.3.6. Orthogonality relations.

The wave functions (93) as eigenfunctions of the Hamiltonians are orthogonal \( n \neq n' \)

\[ \int_0^{\infty} \int_0^{\pi/2} \Psi_{nq_1q_2}^{(\pm k_1, \pm k_2)*}(\nu, \mu; D^2) \Psi_{n'q_1q_2}^{(\pm k_1, \pm k_2)}(\nu, \mu; D^2) dV = 0. \]

(95)

Eqs. (74) and (75) enable one to prove the property of double orthogonality for wave functions \( Z_{nq}^{(\pm k_1, \pm k_2)}(\zeta; D^2) \), namely

\[ \int_0^{\infty} Z_{nq_1}^{(\pm k_1, \pm k_2)*}(i\nu; D^2) Z_{nq_2}^{(\pm k_1, \pm k_2)}(i\nu; D^2) d\nu = 0 \]

(96)

\[ \int_0^{\pi/2} Z_{nq_1}^{(\pm k_1, \pm k_2)*}(\mu; D^2) Z_{nq_2}^{(\pm k_1, \pm k_2)}(\mu; D^2) d\mu = 0 \]

(97)

for \( q_1 \neq q_1' \) and \( q_2 \neq q_2' \), and therefore when \( q \neq q' \)

\[ \int_0^{\infty} d\nu \int_0^{\pi/2} d\mu (\cosh^2 \nu - \cos^2 \mu) \Psi_{nq_1q_2}^{(\pm k_1, \pm k_2)*}(\nu, \mu; D^2) \Psi_{n'q_1q_2}^{(\pm k_1, \pm k_2)}(\nu, \mu; D^2) = 0. \]

(98)

4 Three-dimensional space

So far we have considered only superintegrable systems in two dimensions. To make clearer our approach and how it extends to all dimensions, we consider some 3d examples.
4.1 The harmonic oscillator

As is very well known, the Schrödinger equation for the 3d harmonic oscillator (a superintegrable system) is exactly solvable in Cartesian coordinates. We consider it in elliptic coordinates where the separation equations are QES. We will show explicitly that the polynomial solutions of the uncoupled 3d problem can be found directly and that the results greatly simplify the determination of the polynomial solutions of the separated QES equations. In elliptic coordinates the Schrödinger equation has the form

\[
H = \frac{1}{(u-v)(u-w)}[4\sqrt{P(u)} \frac{\partial}{\partial u}(\sqrt{P(u)} \frac{\partial}{\partial u}) - \omega^2(u^3 - E_1u^2)] \\
+ \frac{1}{(v-u)(v-w)}[4\sqrt{P(v)} \frac{\partial}{\partial v}(\sqrt{P(v)} \frac{\partial}{\partial v}) - \omega^2(v^3 - E_1v^2)] \\
+ \frac{1}{(w-v)(w-u)}[4\sqrt{P(w)} \frac{\partial}{\partial w}(\sqrt{P(w)} \frac{\partial}{\partial w}) - \omega^2(w^3 - E_1w^2)]
\]

where

\[E_1 = e_1 + e_2 + e_3, \quad P(\lambda) = (\lambda - e_1)(\lambda - e_2)(\lambda - e_3).\]

Here the elliptic coordinates are given by

\[x^2 = \frac{(u-e_1)(v-e_1)(w-e_1)}{(e_1-e_2)(e_1-e_3)}, \quad y^2 = \frac{(u-e_2)(v-e_2)(w-e_2)}{(e_2-e_1)(e_2-e_3)}, \quad z^2 = \frac{(u-e_3)(v-e_3)(w-e_3)}{(e_3-e_2)(e_3-e_1)}.\]

The separation equations that describe the solutions of \(H\Psi = E\Psi\) are

\[4\sqrt{P(\lambda)} \frac{\partial}{\partial \lambda}(\sqrt{P(\lambda)} \frac{\partial}{\partial \lambda}) - \omega^2(\lambda^3 + (-E_1 + E)\lambda^2) + L_1\lambda - L_2 \Lambda(\lambda) = 0\]

for \(\lambda = u, v, w\). The operators that describe the separation constants are

\[L_1 = \frac{vw}{(u-v)(u-w)}[4\sqrt{P(u)} \frac{\partial}{\partial u}(\sqrt{P(u)} \frac{\partial}{\partial u}) - \omega^2(u^3 - E_1u^2)] \\
+ \frac{uw}{(v-u)(v-w)}[4\sqrt{P(v)} \frac{\partial}{\partial v}(\sqrt{P(v)} \frac{\partial}{\partial v}) - \omega^2(v^3 - E_1v^2)] \\
+ \frac{uw}{(w-v)(w-u)}[4\sqrt{P(w)} \frac{\partial}{\partial w}(\sqrt{P(w)} \frac{\partial}{\partial w}) - \omega^2(w^3 - E_1w^2)]
\]

and

\[L_2 = \frac{v+w}{(u-v)(u-w)}[4\sqrt{P(u)} \frac{\partial}{\partial u}(\sqrt{P(u)} \frac{\partial}{\partial u}) - \omega^2(u^3 - E_1u^2)] \\
+ \frac{u+w}{(v-u)(v-w)}[4\sqrt{P(v)} \frac{\partial}{\partial v}(\sqrt{P(v)} \frac{\partial}{\partial v}) - \omega^2(v^3 - E_1v^2)] \\
+ \frac{u+w}{(w-v)(w-u)}[4\sqrt{P(w)} \frac{\partial}{\partial w}(\sqrt{P(w)} \frac{\partial}{\partial w}) - \omega^2(w^3 - E_1w^2)]
\]
In order to find square integrable solutions to this problem it is natural to remove an exponential factor according to

\[ \Psi(u, v, w) = \exp\left(-\frac{\omega}{2}(u + v + w)\right)\Phi(u, v, w). \]

Then there are polynomial solutions for \( \Phi(u, v, w) \) of the form

\[ \Phi(u, v, w) = \prod_{j=1}^{r} (u - \theta_j)(v - \theta_j)(w - \theta_j). \]

The zeros of the polynomials satisfy the relations

\[ -4\omega + \sum_{i\neq j} \frac{4}{\theta_i - \theta_j} + \sum_{s=1}^{3} \frac{1}{\theta_j - e_s} = 0 \]

It follows that the eigenvalues \( E \) and \( \ell_1, \ell_2 \) of the operators \( L_1 \) and \( L_2 \) can be expressed in the form

\[ \ell_1 = -4\omega^2 + 2(3 + 4r) \sum_{j=1}^{r} \theta_j + \left[-(1 + 4r)E_2 + 4E_1 \sum_{j=1}^{r} \theta_j - \sum_{j=1}^{r} \theta_j^2 \right] \omega - E_3\omega^2 \]

\[ \ell_2 = -2r(2r + 1) - 2(2r + 1)E_1\omega + 4\omega \sum_{j=1}^{r} \theta_j - E_2\omega^2 \]

where \( E_2 = e_1e_2 + e_2e_3 + e_1e_3 \) and \( E_3 = e_1e_2e_3 \). Because of the relations among the zeros \( \theta_j \) there are also alternative expressions available for these eigenvalues. We now turn our attention to calculating the eigenvalues. Let us first consider the special case \( r = 1 \). If we choose a basis of functions of \( u, v \) and \( w \) \( F_0 = 1, F_1 = u + v + w, F_2 = uv + uw + vw \) and \( F_3 = uvw \) then we can find solutions

\[ \Phi(u, v, w) = a_0F_0 + a_1F_1 + a_2F_2 + a_3F_3. \]

If we look for eigenfunctions for the operator \( L_1 \) that correspond to this form we obtain the conditions

\[ (2E_3\omega^2 + 5E_2\omega + 4E_1 + \ell_1)a_3 + (4E_1\omega + 6)a_2 + 4\omega a_1 = 0, \]

\[ (-2E_2 - 4E_3\omega)a_3 + (\ell_1 + \omega E_2 + \omega^2 E_3)a_2 = 0, \]

\[ (-2E_2 - 4E_3\omega)a_2 + (\ell_1 + \omega E_2 + \omega^2 E_3)a_1 = 0, \quad (-2E_2 - 4E_3\omega)a_1 + (\ell_1 + \omega E_2 + \omega^2 E_3)a_0 = 0. \]

For these equations to have a nontrivial solution the corresponding determinantal condition must hold viz.

\[ (\ell_1 + \omega E_2 + \omega^2 E_3)(\ell_1^2 + (4E_1 + 7E_2\omega + 3E_3\omega^2)\ell_1^2 + \]

\[ (14E_3E_2\omega^3 + (24E_1E_3 + 11E_2^2)\omega^3 + (16E_1E_2 + 24E_3)\omega + 12E_2)\ell_1 + \]

\[ E_3(20E_1E_3 + 11E_2^2)\omega^4 + (5E_3^2 - 188E_2E_3 + 32E_1E_2E_3)\omega^3 + 4E_2(6E_1E_2 - 14E_3)\omega^2 + 28E_2\omega) = 0. \]

For the operator \( L_2 \) the corresponding relations among the \( a_i \) are

\[ (6 + \ell_2 + E_2\omega^2 + 6\omega E_1)a_3 + 4\omega a_2 = 0, \quad (6 + \ell_2 + E_1\omega + E_2\omega^2)a_2 + 4\omega a_3 = 0, \]

\[ -(6 + \ell_2 - 4E_3\omega)a_3 + (4E_2\omega + 4E_1)a_2 + (E_2\omega^2 + 2\omega E_1 + \ell_2)a_1 = 0, \]

\[ 20 \]
\[-(2E_2 - 4E_3\omega)a_2 + (-4E_1 + 4E_2\omega)a_1 + (\ell_2 + 2E_1\omega + E_2\omega^2)a_0 = 0,\]

with the determinantal condition
\[(\ell_2 + 2\omega E_1 + \omega^2 E_2)(\ell_2^5 + (14\omega E_1 + 3\omega^2 E_2)\ell_2^4
\quad \quad + (3\omega^4 E_2^2 + 28\omega^3 E_1 E_2 + \omega^2 (60 E_1^2 + 40 E_2) + 112\omega E_1 + 36)\ell_2
\quad \quad + \omega^6 E_2^3 + 14\omega^5 E_1 E_2^2 + 4\omega^4 E_3 (15 E_1^2 + 7 E_2) + \omega^3 (72 E_1^3 + 208 E_1 E_2 - 343 E_3)
\quad \quad + \omega^2 (240 E_1^2 + 100 E_2) + 168\omega E_1)) = 0.\]

This illustrates clearly that our method gives the eigenvalues of \(L_1\) and \(L_2\) as solutions of polynomial equations. If we substitute in this way into the Schrödinger equation itself then we obtain the conditions
\[(E + 7\omega)a_j = 0, \quad j = 1, 2, 3,\]
\[(2E_2 + 4E_3\omega)a_3 + 4(E_1 + \omega E_2)a_2 + 2(3 + 2\omega E_1)a_1 - (E + 3\omega)a_0 = 0\]
yielding the two eigenvalues \(-7\omega\) and \(-3\omega\) for \(E\). This method has obvious extensions to \(r = 2, \ldots\).

Note that if we look for polynomial solutions of the separation equations then we obtain different equations. In particular if we look for solutions of the form \(\Lambda(\lambda) = \exp(-\frac{\omega}{2}\lambda)(\lambda - c)\) in the separation equation
\[\sqrt{P(\lambda)} \frac{\partial}{\partial \lambda}(\sqrt{P(\lambda)} \frac{\partial}{\partial \lambda} \Lambda(\lambda)) + (\omega^2 (-\lambda^3 + (E_1 - E)\lambda^2) + \ell_2 \lambda - \ell_1) \Lambda(\lambda) = 0\]
we obtain the relations
\[\ell_2^2 + \ell_2(6 + 8\omega E_1 + 2\omega^2 E_2) + 4\omega \ell_1 + \omega^2 E_2^2 + \omega^3 (8E_1E_2 + 4E_3) + \omega^2 (12E_1^2 + 26E_2) + 28\omega = 0,\]
\[\ell_1 \ell_2 + \omega (E_2 + E_3 \omega) \ell_2 + \omega (6E_1 + \omega E_2) \ell_1 + E_2 E_3 \omega^4 + \omega^3 (6E_1 E_3 + E_2^2) + \omega^2 (6E_1 E_2 + 22E_3) + 14E_2 \omega = 0,\]
where
\[c = ((12 + 2\ell_2) + 6\omega E_1 + \omega^2 E_2) / 4\omega.\]

If we were to pursue this approach further then we would obtain more complicated relations among the \(\ell_1\) and \(\ell_2\) which could be uncoupled to produce the individual equations for \(\ell_1\) and \(\ell_2\) respectively. This example shows clearly how study of the full 3d superintegrable system yields results for solutions of the separation equations that could not easily be obtained from a direct study of the separation equations themselves.

### 4.2 Ushveridze’s separation of variables example

A critical further example is that studied by Ushveridze on page 115 of his book [63]. He takes two copies of an ordinary differential QES problem (polynomial potential of order 10) and combines them to form a single 2d partial differential equation from which the original ordinary differential equations can be obtained by separation of variables. However, the partial differential equation that he obtains is merely separable, not multiseparable. In particular it is not superintegrable. Here we show the increased insight and greater simplicity obtained by
using three copies of the QES problem to form a 3d superintegrable system. We proceed as
follows. Consider the Schrödinger equation $H\Psi = E\Psi$ where

$$
H = \frac{1}{(u^2 - v^2)(u^2 - w^2)} \left[ \frac{\partial^2}{\partial u^2} - 36k_1^2u^{10} - 48k_1k_2u^8 - 8(2k_2^2 + 3k_1k_3)u^6 + \frac{p(1-p)}{u^2} \right] \\
+ \frac{1}{(v^2 - u^2)(v^2 - w^2)} \left[ \frac{\partial^2}{\partial v^2} - 36k_1^2v^{10} - 48k_1k_2v^8 - 8(2k_2^2 + 3k_1k_3)v^6 + \frac{p(1-p)}{v^2} \right] \\
+ \frac{1}{(w^2 - u^2)(w^2 - v^2)} \left[ \frac{\partial^2}{\partial w^2} - 36k_1^2w^{10} - 48k_1k_2w^8 - 8(2k_2^2 + 3k_1k_3)w^6 + \frac{p(1-p)}{w^2} \right].
$$

This equation is clearly separable in the $u, v, w$ coordinates. Passing to Cartesian coordinates
$z = iu vw$ and

$$
x + iy = \frac{1}{2}(u^2 v^2 + u^2 w^2 + v^2 w^2) - \frac{1}{4}(u^4 + v^4 + w^4), \quad x - iy = \frac{1}{2}(u^2 + v^2 + w^2),
$$

we can recognize the Hamiltonian operator in the form

$$
H = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} + 36k_1^2(2(x - iy)^3 - 4(x^2 + y^2) - z^2) + 48k_1k_2(3(x - iy)^2 - (x + iy)) - 16(2k_2^2 + 3k_1k_3)(x + iy) - \frac{p(p-1)}{z^2}.
$$

(99)

This in turn can be recognized as essentially the complex Euclidean space superintegrable
system with nondegenerate potential

$$
V = \alpha \left( z^2 - 2(x - iy)^3 + 4(x^2 + y^2) \right) + \beta \left( 2(x + iy) - 3(x - iy)^2 \right) + \gamma(x + iy) + \delta \frac{1}{z^2},
$$

(100)

in which the six basis second-order symmetry operators can be taken in the form

$$
H = \partial_x^2 + \partial_y^2 + \partial_z^2 + V,
$$

(101)

$$
S_1 = (\partial_x - i\partial_y)^2 + f_1, \quad S_2 = \partial_x^2 + f_2, \quad S_3 = \{\partial_z, J_2 + iJ_1\} + f_3,
$$

$$
S_4 = \frac{1}{2}\{J_3, \partial_x - i\partial_y\} - \frac{i}{4}(\partial_x + i\partial_y)^2 + f_4, \quad S_5 = (J_2 + iJ_1)^2 + 2\{\partial_z, J_1\} + f_5,
$$

where $\{A, B\} = AB + BA$, the $J_i$ are the angular momentum operators, e.g., $J_3 = x\partial_y - y\partial_x$, and the $f_i$ are appropriate functions. There is a quadratic algebra generated by these
symmetries. This is a direct consequence of the observation that this potential is an example of
a nondegenerate potential in three dimensions,[7, 8].

The separation equations for the Schrödinger equation have the form

$$
[\frac{\partial^2}{\partial \lambda^2} - 36k_1^2\lambda^{10} - 48k_1k_2\lambda^8 - 8(2k_2^2 + 3k_1k_3)\lambda^6 + \frac{p(1-p)}{\lambda^2} + E\lambda^4 + \ell_2\lambda^2 + \ell_3]\Lambda(\lambda) = 0,
$$

22
essentially, Uskveridze’s 1d QES problem. The operators with the separation constants as eigenvalues are

\[
L_2 = \frac{v^2 + w^2}{(u^2 - v^2)(u^2 - w^2)} \frac{\partial^2}{\partial u^2} - 36k_1^2u^{10} - 48k_1k_2u^8 - 8(2k_2^2 + 3k_1k_3)u^6 + \frac{p(1-p)}{u^2} \quad (102)
\]

\[
+ \frac{u^2 + w^2}{(u^2 - v^2)(u^2 - w^2)} \frac{\partial^2}{\partial v^2} - 36k_1^2v^{10} - 48k_1k_2v^8 - 8(2k_2^2 + 3k_1k_3)v^6 + \frac{p(1-p)}{v^2}
\]

\[
+ \frac{u^2 + v^2}{(w^2 - v^2)(w^2 - u^2)} \frac{\partial^2}{\partial w^2} - 36k_1^2w^{10} - 48k_1k_2w^8 - 8(2k_2^2 + 3k_1k_3)w^6 + \frac{p(1-p)}{w^2}
\]

and

\[
L_3 = \frac{v^2w^2}{(u^2 - v^2)(u^2 - w^2)} \frac{\partial^2}{\partial u^2} - 36k_1^2u^{10} - 48k_1k_2u^8 - 8(2k_2^2 + 3k_1k_3)u^6 + \frac{p(1-p)}{u^2} \quad (103)
\]

\[
+ \frac{u^2w^2}{(u^2 - v^2)(u^2 - w^2)} \frac{\partial^2}{\partial v^2} - 36k_1^2v^{10} - 48k_1k_2v^8 - 8(2k_2^2 + 3k_1k_3)v^6 + \frac{p(1-p)}{v^2}
\]

\[
+ \frac{u^2v^2}{(w^2 - v^2)(w^2 - u^2)} \frac{\partial^2}{\partial w^2} - 36k_1^2w^{10} - 48k_1k_2w^8 - 8(2k_2^2 + 3k_1k_3)w^6 + \frac{p(1-p)}{w^2}.
\]

In searching for finite solutions of \( H \Psi = E \Psi \) we write

\[
\Psi(u, v, w) = \exp(k_1(u^6 + v^6 + w^6) + k_2(u^4 + v^4 + w^4) + k_3(u^2 + v^2 + w^2))(uvw)^p\Phi(u, v, w)
\]

where

\[
\Phi(u, v, w) = \Pi_{j=1}^r (u^2 - \theta_j)(v^2 - \theta_j)(w^2 - \theta_j).
\]

The zeros of the polynomials satisfy the relations

\[
\frac{2r + 1}{2\theta_i} - 12k_1\theta_i^2 - 4k_2\theta_i - k_3 + \sum_{j \neq i} \frac{1}{\theta_i - \theta_j} = 0.
\]

Solving these equations we see that the eigenvalues of the operators \( H, L_2 \) and \( L_3 \) have the form

\[
E = -(30 + 24r + 12p)k_1 - 16k_2k_3, \quad \ell_2 = -4k_3^2 - (12 + 16r)k_2 - 24k_1 \sum_{j=1}^r \theta_j,
\]

\[
\ell_3 = -(2 + 8r + 4p)k_3 - 16k_2 \sum_{j=1}^r \theta_j - 24k_1 \sum_{j=1}^r \theta_j^2.
\]

Because of the relations among the zeros there are many other expressions for these eigenvalues. If we look for solutions of the form

\[
\Phi(u, v, w) = a_0G_0 + a_1G_1 + a_2G_2 + a_3G_3
\]

where \( G_0 = 1, G_1 = u^2 + v^2 + w^2, G_2 = u^2v^2 + u^2w^2 + v^2w^2 \) and \( G_3 = u^2v^2w^2 \), i.e., second order polynomial solutions, and substitute this expression into the eigenvalue equations, we obtain the following polynomial equations for the eigenvalues

23
\[(E + k_1(54 + 12p))^2(E + k_1(30 + 12p)) = 0,\]
\[(\ell_2 + 2k_2(4p + 1) + 4k_3^2)(\ell_2 + (12k_3^2 + 68 + 24p)k_2)\ell_2^2 + (192k_1k_3 + 16(2p + 7)(6p + 13)k_2^2 + 32k_3^2k_2(6p + 17) + 48k_3^2)\ell_2 + 64(17 + 6p)k_2k_3^2 + 768k_1k_3^3 + 64(2p + 7)(6p + 13)k_2^2k_3^3 + 768(2p + 7)k_1k_2k_3 + 64(2p + 3)(2p + 7)^2k_3^2 - 1152(2p + 1)k_1^2 = 0,\]
\[(\ell_3 + 2k_3(p + 1))(\ell_3^2 + 2(6p + 7)k_3\ell_3^2 + 4(6p + 11)(1 + 2p)k_3^2\ell_3 + 8(1 + 2p)^2(12k_1 + 2p k_3^2 + 5k_3^3)) = 0.\]

On the other hand, if we study the separation equations individually and look for a solution of the form

\[\Lambda(\lambda) = \exp(k_1\lambda^6 + k_2\lambda^4 + k_3\lambda^2)\lambda^p(\lambda - c)\]

in the above separation equation then we obtain different relations

\[\ell_2^2 + (4k_2(10 + 4p) + 8k_3^2)\ell_2 + 24k_1\ell_3 + 16k_3^4 + 8(4k_2k_3^2 + 6k_1k_3)(5 + 2p) + 16k_2^2(2p + 7)(2p + 3) = 0,\]
\[\ell_2\ell_3 + 2(2p + 1)\ell_2 + (4k_2(2p + 7) + 4k_3^2)\ell_3 + 48k_1(1 + 2p) + 8k_2k_3(2p + 7)(2p + 1) + 8(1 + 2p)k_3^3 = 0,\]
where
\[c = -\frac{1}{24k_1}(4k_2(p + 7) + 4k_3^2 + \ell_2).\]

The above computation extends in an obvious manner to the computation of polynomial solutions of any order. There is a clear relationship with Usveridze’s equation on page 115 of [63] through the correspondence \(a = 6k_1, b = 4k_2, c = 2k_3\) and \(s = (2p + 1)/4.\)

We now look for solutions determined by other second order constants of the motion and corresponding (possibly separable) coordinate systems. First consider our basic equation \(H\Psi = E\Psi\) written in terms of different coordinates \(\xi = x + iy, \eta = x - iy, z.\) We can find nonseparable solutions in these coordinates of the form

\[\Psi = \exp(2\sqrt{[\lambda + (k_2 + 3k_1\xi)^2]}\eta\]

\[\int[-\frac{3k_1(k_2 + 3k_1\xi)}{[\lambda + (k_2 + 3k_1\xi)^2]} + \frac{\xi(-9k_1^2\xi^2 + 9k_1k_2\xi + 6k_1k_2 + 4k_3^2) + E}{\sqrt{[\lambda + (k_2 + 3k_1\xi)^2]}}]d\xi\]

\[\exp(-3k_1z^2)z^pL_{n}^{p+\frac{1}{2}}(6k_1z^2)\]

where
\[E = E - 6k_1(4n + 2p + 1)\]

and \(L_{n}^{n}(t)\) is a Laguerre polynomial. It is clear that the above \(\xi\) integral can be calculated in terms of elementary functions but we prefer the form given as it is more compact. This possibility for an explicit solution comes about from the existence of a symmetry of the form \(p^2 + f.\)

If we choose new separable coordinates \(u, v, z\) defined by

\[x + iy = -\frac{1}{2}(u - v)^2, \quad x - iy = u + v\]

24
then the Schrödinger equation has the separable form
\[
H\Psi = \left[ \frac{1}{u-v}(\frac{\partial}{\partial u^2} - 144k_1^2u^4 - 96k_1k_2u^3 + 16(2k_2^2 + 3k_1k_3)u^2) - \frac{\partial^2}{\partial v^2} - 144k_1^2v^4 - 96k_1k_2v^3 + 16(2k_2^2 + 3k_1k_3)v^2\right] + \frac{p(1-p)}{z^2} \Psi = E\Psi.
\] (104)

The symmetry operator \( L \) associated with separation in these coordinates is of the form
\[
L\Psi = \left[ \frac{1}{u-v}v\left(\frac{\partial}{\partial u^2} - 144k_1^2u^4 - 96k_1k_2u^3 + 16(2k_2^2 + 3k_1k_3)u^2\right) - u\left(\frac{\partial}{\partial v^2} - 144k_1^2v^4 - 96k_1k_2v^3 + 16(2k_2^2 + 3k_1k_3)v^2\right)\right] \Psi.
\]

Searching for finite solutions using these coordinates, we see that they can be taken in the form
\[
\Psi = \exp(4k_1(u^3 + v^3) + 2k_2(u^2 + v^2) - 2(k_2^2 + k_3)(u + v))\Pi_{i=0}^{r}((u - \theta_i)(v - \theta_i)) \times \exp(-3k_1z^2) z^{\frac{p-1}{2}} (6k_1z^2).
\]

For solutions of this kind these zeros satisfy
\[
-2k_1k_3 - 2k_2^2 + 4k_1k_2 \sum_{i=1}^{r} \theta_i + 12k_2^2 \sum_{i=1}^{r} \theta_i^2 + \sum_{j \neq i} \frac{k_1}{\theta_i - \theta_j} = 0.
\]

The eigenvalues of \( L \) and \( H' \) have the form
\[
\lambda_r = -4\frac{k_1^3}{k_1^3} - 8\frac{k_2^2k_3}{k_1} - 4k_3^2 - 4(1+2r)k_2 - 24 \sum_{i=1}^{r} \theta_i, \quad E_r = 16k_2k_3 + 16\frac{k_3^3}{k_1} - 24(r + 1)k_1,
\]

and \( E = E_r + 6k_1(4n + 2p + 1). \)

It is clear that we can find solutions of the form given above but with a choice of polynomial, say \( c_1uv + c_2(u + v) + c_3 \) for illustration. The resulting polynomial equation for the eigenvalues of \( L \) is
\[
\left(\lambda k_1^2 + 4k_2^2k_3^2 + 4k_2k_1^4 + 4k_3^2 + 8k_1k_3k_2^3\right)\left(k_1^4\lambda^2 + 8k_1^3\left(2k_2k_1^2 + k_3^2\right) + 2k_1k_3k_2^2 + k_2^4\right)\lambda
-96k_3k_1^5 - 48k_2^2k_1^4 + 64k_2^2k_1^4k_2 + 16k_3^4k_1^4 + 128k_3^2k_3k_1^3 + 64k_3^3k_3^2k_2^2 + 64k_2^5k_1^2 + 96k_1^2k_2^4k_3^2
+64k_2^5k_1k_3 + 16k_2^5 = 0.
\]

These are finite solutions, clearly different from those given previously. The above analysis can be extended in an obvious manner to yield polynomial solutions of any order.

Note that for this last coordinate system we have given an example of a QES problem with a quartic potential, something hitherto not known to be possible (as mentioned in Ushveridze’s book). Indeed the separation equations have the form
\[
\frac{\partial^2}{\partial \ell^2} - 144k_1^2\ell^4 - 96k_2k_1\ell^3 + 16(2k_2^2 + 3k_1k_3)\ell^2 - \left\{16k_2k_3 + 16\frac{k_3^2}{k_1} + 6k_1(4n - 4r + 2p - 3)\right\}\ell + \lambda_r \} A(\ell) = 0
\]

25
where \( \Lambda = U, V \) and \( \ell = u, v \). There are typically \( r + 1 \) solutions

\[
\Lambda(\ell) = \exp(4k_1\ell^3 + 2k_2\ell^2 - 2\left(\frac{k_2^2}{k_1} + k_3\ell\right)\Pi_{i=0}^r(\ell - \theta_i)
\]

of this equation, with corresponding eigenvalues \( \lambda_i^{(s)}, s = 1, \ldots, r+1 \). It is clear from our definition of QES that if we look for series solutions then the recurrence relations involved will contain more than three terms. The analysis then proceeds in analogy with what has been demonstrated for the case of three terms and the requirement of polynomial solutions (to within a factor) is a consequence of the solutions generated in this manner being well behaved at the regular singular points.

It is clear that in higher dimensions there are many examples which generalize the examples occurring in [63]. The utility of the use of partial differential operators, rather than ordinary differential operators, is evident. Finally, we note in the superintegrable example presented here, though our system is multiseparable there are no separable coordinates in which the separated equations are each exactly solvable.

5 Conclusions and summary

We have demonstrated that solutions of the Schrödinger equation for the potential \( V_1 \) may be constructed via separation of variables in two different ways. Using Cartesian coordinates we arrive at two independent exactly solvable equations (17) and (18), each of them representing a one-dimensional non-parametric spectral problem where the Cartesian separation constants \( \lambda_i \) play the role of energy. To obtain solutions in the form of Laguerre and Hermite polynomials, both separation constants are quantized and as a result the energy spectrum for the two-dimensional Schrödinger equation is obtained. For the second separable system which uses parabolic coordinates the solution method is more complex. We have shown that the separation procedure reduces to an ordinary differential equation for real and imaginary variables. It has been proven that the requirement of convergence for solutions of eq. (30) at the singular points \( \mu = \pm \infty \) and \( \mu = \pm \infty \) leads to only polynomial solutions (42) with the restriction for the energy spectrum \( E \) in the form (22) and for a fixed energy (or quantum number \( n \)) gives the spectrum of the separation constant as the root of an \( n \)th-degree polynomial equation. In contrast to the solution in Cartesian coordinates the coefficients of the polynomial solutions satisfy three-term recurrence relations and cannot be written in explicit form in general. For this reason we refer to the equation (30) as quasi-exactly solvable.

On the other hand, the substitution of the formula for the energy spectrum into eq. (30) gives rise to the equation

\[
\left[ -\frac{d^2}{d\mu^2} + \left( \omega^2 \mu^6 + k_1 \mu^4 + \left( \frac{k_1^2}{4\omega^2} - \omega(4n + 4 \pm 2k_2) \right) \mu^2 + \frac{k_2^2 - \frac{1}{2}}{\mu^2} \right) \right] Z_n(\mu) = \lambda Z_n(\mu), \tag{105}
\]

which on the real axis completely coincides for \( k_1 = 4\beta \omega^2 \) and \( 1 \pm k_2 = 2\delta \), with the one-dimensional spectral problem (10), and is called a quasi-exactly solvable problem. Now it is easy to understand the origins of the occurrence of quasi-exactly solvable systems. The requirement of convergence just in real space (which is possible to determine following [37] as the dimensional reduction) in the vicinity of singular points \( \mu = \pm \infty \) requires that there are
polynomial solutions of the form (41). We also can shed light on the mystery of the zeros of the polynomial \( P_n(x^2) \). Indeed, the substitution of the wave function (11) into the Schrödinger equation with potential (10) leads to the differential equation for polynomial \( P_n(x^2) \) in the same form as equation (58) (in variable \( x^2 = z \)), but with the difference that the physical region of eq. (58) is the whole real axis \( z \in (-\infty, \infty) \), and therefore all zeros (for positive and negative \( x^2 \)) of \( P_n(x^2) \) correspond to the zeros of two-dimensional eigenfunction of singular anisotropic oscillator in parabolic coordinates.

The situation is repeated in the case of the second potential (60). We have determined that the separation of variables in two-dimensional elliptic coordinates leads to a Schrödinger type equation (76) in the complex plane and the requirement of convergence at the point \( \zeta = 0,2\pi \) and \( \zeta = i\infty \) requires polynomial solutions and defines the energy spectrum (66). As a consequence trigonometric and hyperbolic quasi-exactly solvable systems (see potentials 5 and 8 in [61]) are generated in the form

\[
\frac{d^2X}{du^2} + \left[ \left( \frac{\alpha^2}{4} + \alpha(2n + 2 \pm k_1 \pm k_2) \right) \cosh^2 \nu - \frac{\alpha^2}{4} \cosh^4 \nu - \frac{k_1^2 - \frac{1}{4}}{\sinh^2 \nu} + \frac{k_2^2 - \frac{1}{4}}{\cosh^2 \nu} + \lambda \right] X = 0,
\]

\[
\frac{d^2Y}{d\mu^2} - \left[ \left( \frac{\alpha^2}{4} + \alpha(2n + 2 \pm k_1 \pm k_2) \right) \cos^2 \mu - \frac{\alpha^2}{4} \cos^4 \mu + \frac{k_1^2 - \frac{1}{4}}{\cos^2 \mu} + \frac{k_2^2 - \frac{1}{4}}{\sin^2 \mu} + \lambda \right] Y = 0,
\]

where \( \alpha = D^2\omega/2 \). Thus we have established that an integral part of the notion of quasi-exact solvability is the reduction of superintegrable systems to one dimensional problems.

Indeed, we can express our observation in the form of the following hypothesis: All quantum-mechanical problems which are expressible as one-dimensional quasi-exactly solvable systems can be determined via separation of variables in an N-dimensional Schrödinger equation for superintegrable systems.

This analogy prompts us to use the term quasi-exact solvability for the equations of type (30) or (76), defined in the complex plane and which are not exactly solvable but which admit polynomial solutions. Thus we suggest calling quantum mechanical systems first-order quasi-exactly solvable if the polynomial solution of the one-parametric differential equation of the kind of Schrödinger equation or N-dimensional equation after separation of variables is defined through recurrence relations which must always contain three terms or more and the discrete eigenvalues can be calculated as the solutions of algebraic equations. According to this definition systems (30) and (76) are first order quasi-exactly solvable.

In 3 dimensions we have provided even more striking examples of 1d QES problems obtained as restrictions from superintegrable systems. We exhibited a quasi-exactly solvable superintegrable system which is not at the same time exactly solvable in any separable set of coordinates. In one set of separable coordinates we obtain Ushveridze’s 10th order polynomial QES problem and in another set a 4th order polynomial QES problem. We have shown how the eigenvalues of the symmetry operators which describe separation can be calculated from a determinantal condition. These examples, and more to come on other manifolds and in higher dimensional spaces, indicate that our modified definition of QES systems can be extended to N-dimensional spaces and fine tuned to distinguish between the number of parameters in the systems. These matters will be taken up in other papers in this series.

Appendix: Asymptotic behavior of coefficients

To understand the behavior of the solutions of relations (36) for large \( s \) we use continued fractions theory [81]. Setting

\[
\frac{A_s}{A_{s-1}} = \xi_s f(s) \tag{106}
\]

\[
f(s) = \sqrt{\frac{\Gamma\left(\frac{s}{2} + \frac{1}{2}\right)\Gamma\left(\frac{s}{2} + \frac{s + 1}{2}\right)}{\Gamma\left(\frac{s}{2} + 1\right)\Gamma\left(\frac{s}{2} + \frac{s + 1}{2}\right)}} \cdot \frac{\Gamma\left(\frac{s}{2} + \frac{s + 1}{2}\right)}{\Gamma\left(\frac{s}{2} + 1\right)} \left[\lambda \pm \frac{k_1}{\omega^2} \right],
\]

where \( \Gamma(z) \) is the Gamma function, we can write the recurrence relation (36) in the standard form

\[
\xi_s = \frac{1}{b_s + \xi_{s+1}}, \tag{107}
\]

\[
b_s = \sqrt{\frac{\Gamma\left(\frac{s}{2} + \frac{1}{2}\right)\Gamma\left(\frac{s}{2} + \frac{s + 1}{2}\right)}{\Gamma\left(\frac{s}{2} + 1\right)\Gamma\left(\frac{s}{2} + \frac{s + 1}{2}\right)}} \left[\lambda \pm \frac{k_1}{\omega^2} \right] 2^s,
\]

where \( \alpha = -(E + k_1/(8\omega^2))/2 \). Note that

\[
f(s + 1)f(s) = \omega \frac{(\frac{s}{2} + k_2 + s + 1)}{(s + 1)(\frac{s}{2} + k_2 + s + 1)}.
\]

Stirling’s formula for the Gamma function \( \Gamma(z) = z^{z-1/2}e^{-z}\sqrt{2\pi}(1 + O(1/z)) \) as \( |z| \to \infty \) with \( |\arg z| < \pi \), gives \( f(s) = -\sqrt{\frac{2\pi}{s}}(1 + O(1/s)) \) and \( b_s = \pm \frac{k_1}{2\omega\sqrt{\omega}}(1 + O(1/s)) \). In the following we take \( k_1 \leq 0, k_2, \lambda, E \) real and \( \omega > 0 \). Without loss of generality we can assume \( b_s \) is positive for sufficiently large \( s \) since, otherwise, we could make the replacements \( b_s \to -b_s, \xi_s \to -\xi_s \).

Since \( \sum b_s = \infty \), it is a consequence of the Seidel-Stern theorem that the formal continued fraction expressions for the \( \xi_s \) converge:

\[
\xi_s = \frac{1}{b_s + \frac{1}{b_{s+1} + \ldots + b_{s+k} + \ldots}}.
\]

Moreover, standard continued fraction theory tells us that

\[
\xi_s = \lim_{n \to \infty} \frac{A_n^{(s)}}{B_n^{(s)}}, \tag{108}
\]

where

\[
\begin{pmatrix}
A_{n-1}^{(s)} \\
B_{n-1}^{(s)}
\end{pmatrix} = \begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix}, \quad \begin{pmatrix}
A_0^{(s)} \\
B_0^{(s)}
\end{pmatrix} = \begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}, \tag{109}
\]

and

\[
\begin{pmatrix}
A_n^{(s)} \\
B_n^{(s)}
\end{pmatrix} = b_{n+s} \begin{pmatrix}
A_{n-1}^{(s)} \\
B_{n-1}^{(s)}
\end{pmatrix} + \begin{pmatrix}
A_{n-2}^{(s)} \\
B_{n-2}^{(s)}
\end{pmatrix}, \quad n \geq 1.
\]
Furthermore the relation \( A_n^{(s)} B_{n-1}^{(s)} - A_{n-1}^{(s)} B_n^{(s)} = (-1)^n n \) holds for all \( n \geq 0 \), which implies
\[
\frac{A_n^{(s)}}{B_n^{(s)}} - \frac{A_{n-1}^{(s)}}{B_{n-1}^{(s)}} = \frac{(-1)^n n}{B_{n-1}^{(s)} B_n^{(s)}}.
\]

This result in turn implies that the sequence \( A_n^{(s)} B_{2n}^{(s)} \) is, for large \( s \) and \( n \), monotone increasing in \( n \) and goes to \( \xi_s \) in the limit, whereas \( A_{2n+1}^{(s)} B_{2n+1}^{(s)} \) is monotone decreasing in \( n \) and goes to \( \xi_s \) in the limit. For example,
\[
\frac{A_{2n+2}^{(s)}}{B_{2n+2}^{(s)}} - \frac{A_{2n}^{(s)}}{B_{2n}^{(s)}} = \frac{b_{2n+2+s}}{B_{2n+2}^{(s)}}.
\]  

It follows from (108), (110) that
\[
\xi_s = \frac{A_0^{(s)}}{B_0^{(s)}} + \sum_{n=1}^{\infty} \frac{b_{2n+2+s}}{B_{2n}^{(s)} B_{2n+2}^{(s)}}.
\]  

Simple estimates using the recurrence relations (109) give
\[
B_{2n}^{(s)} > 1 + b_{s+1} \sum_{m=1}^{n} b_{2m+s}, \quad B_{2n+1}^{(s)} > \sum_{m=0}^{n} b_{2m+1+s}.
\]

Substituting these results into the identities
\[
B_{2n}^{(s)} = \sum_{m=1}^{n} b_{2m+s} B_{2m-1}^{(s)}, \quad B_{2n+1}^{(s)} = \sum_{m=0}^{n} b_{2m+s+1} B_{2m}^{(s)}
\]

we get refined upper bounds for \( B_{2n}^{(s)}, B_{2n+2}^{(s)} \). We can approximate the sum \( \sum_{m=0}^{n} 1/\sqrt{m} \) by the integral \( \int_{0}^{\infty} \frac{dy}{\sqrt{y^2 + 1}} \) and use similar approximations to get an upper bound for the series (111):
\[
|\xi_s| < \kappa_1 \int_{0}^{\infty} \frac{dy}{\sqrt{y^2 + 1}} + \kappa_2
\]

for positive constants \( \kappa_i \) independent of \( s \). This shows that \( |\xi_s| \) is uniformly bounded in \( s \). Since \( \xi_{s+1} = -b_s + 1/\xi_s \) and \( b_s \to 0 \) as \( s \to \infty \) it is also true that \( |1/\xi_s| \) is uniformly bounded in \( s \).

It follows from (107) that
\[
\xi_{s+1} - \xi_{s-1} = \frac{\xi_{s-1} - (b_s + \xi_{s-1}) (1 - b_{s-1} \xi_{s-1})}{1 - b_{s-1} \xi_{s-1}}.
\]

Now choose \( s_0 \) so large that \( b_{s+1} < b_s \) and \( b_s \xi_{s} < 1 \) for all \( s \geq s_0 \). Note from this identity that if \( \xi_{s-1} > 1 \) for some \( s_1 > s_0 \) then \( \xi_{s+1} > \xi_{s-1} > 1 \). Thus the sequence \( \xi_{s+2k-1} \) is monotonically increasing for all \( k \geq 0 \). Since \( |\xi_s| \) is bounded, it follows that in this case \( \lim_{k \to \infty} \xi_{s+2k-1} = \xi_+ \) exists, and \( \xi_+ > 1 \). Since \( \xi_{s+1} = -b_s + 1/\xi_s, b_s \to 0 \) as \( s \to \infty \) and \( |1/\xi_s| \) is uniformly bounded in \( s \), then the sequence \( \xi_{s+2k} \) is also convergent, \( \lim_{k \to \infty} \xi_{s+2k} = \xi_- \) where \( 0 < \xi_- < 1 \).

The other possibility is that \( \xi \leq 1 \) for all \( s \geq s_0 \). Since \( 1/\xi_s - \xi_{s+1} = b_s \to 0 \) as \( s \to \infty \), and \( 1/\xi_s \geq 1, \xi_{s+1} \leq 1 \) for all \( s \geq s_0 \) it follows that \( \lim_{k \to \infty} \xi_k = \xi_+ = \xi_- = 1 \). Thus in all cases the sequences \( \xi_{2k} \) and \( \xi_{2k+1} \) converge.
We conclude that

\[
\frac{A_{s+1}}{A_s} = f(s + 1)\xi_s = \sqrt{\frac{\omega\xi_+}{s}}(1 + O(1/s)), \quad \xi_+\xi_- = 1,
\]

depending on whether \( s \) is even or odd.
